and to the right of the umbilicus. The patient was suffering from severe shock and his general condition was that of collapse; he appeared to be drowsy and somnolent, but took notice when spoken to, and complained of severe pain in the abdomen, which was extremely tender in the region of the bruising. His pulse was hardly countable, being exceedingly small and quick. The temperature was 97°. The abdomen was rigid, tense, immobile and slightly distended. There were no symptoms of spinal injury. A catheter was passed into the bladder and about four ounces of urine were drawn off, clear and free from blood. He again vomited soon after admission. His countenance was pale and anxious-looking, and he was covered with a rather profuse cold perspiration; the lips were pale and dry, and there was considerable thirst; the respiration was thoracic in type, quick and shallow. He lived for twenty-five hours after admission; his condition throughout continued to be much the same as when admitted. He passed urine once naturally. There was no evacuation of the bowel and no flatus expelled. He vomited three times while in hospital; the last time, which occurred immediately before death, the vomit was stercoraecous. The abdomen was gradually getting more distended. The patient became rather delirious and took to lying on his back. About twenty minutes before death the patient, who a short time previously to that had become a little excited and restless, jerked himself up suddenly in bed and fell back with a loud groan, senseless and pulseless, expiring without again recovering consciousness.

The treatment consisted in wrapping the patient warmly in blankets and applying hot bottles. Ether was given subcutaneously and a little hot stimulant administered by the mouth; hot fomentations were applied over the abdomen and morphia given hypodermically to allay pain. A little fluid nourishment was also given and retained. The necropsy, two days after death, yielded the following results: Peritonæum, both visceral and parietal, and the omentum were reddened and hyperæmic; no flakes of lymph. The small intestine was carefully examined inch by inch; starting at the cæcum about a foot and a half above the ileo-cæcal valve, the intestine was found to be completely cut across and its mesentery deeply lacerated. The cut ends of the intestine were dark in colour, bruised and bloodstained; the abdominal cavity contained a large quantity of blood. The other abdominal organs were normal. Nothing unusual was found in any other part of the body.

### THE GESTO HOSPITAL, SKYE.

#### A CASE ILLUSTRATING THE SUCCESSFUL TREATMENT OF INTERNAL HÆMORRHOIDS BY CHRYSAROBIN.

(Under the care of Dr. KEITH NORMAN MACDONALD.)

THE success which attended the application of chrysarobin in the following case renders it worthy of being placed on record. It would be interesting if others of our readers who have tried this remedy would give us their experience of its use. On July 9th, 1892, D. M.—, aged sixty-one, was admitted into the Gesto Hospital suffering from bleeding hæmorrhoids. He seemed very feeble, anæmic and emaciated from loss of blood, tottering in his gait, and altogether he appeared a rather unpromising-looking subject. His family history was good, and he himself enjoyed robust health up to about six years ago, when, in consequence of a fall from a scaffold, he felt some weakness of the spine for which he was treated in the Glasgow Royal Infirmary, but has ever since suffered more or less from atrophy and weakness of the lower extremities. His first attack of hæmorrhoids occurred two years ago, and in October, 1890, he had them ligatured, and made a good recovery at the time. His present attack commenced three months ago, and ever since then he has been losing more or less blood with almost every evacuation of the bowels, and the "lump" which came down he described as being as large as a hen's egg, which often took him fifteen minutes, and even half an hour or more, before he could return it into the bowel. On the morning following his admission—a drachm of compound liquorice powder having been administered the night before—it was found that a mass of hæmorrhoids, fully as large as a Tangerine orange, occupied the cleft of the nates, from which arterial blood escaped on attempting reduction; but this was effected after free lubrication with carbolic oil. The proper line of treatment was clear enough—viz., to arrest the hæmorrhage by surgical procedure; but, owing to the state

of his general health and all the circumstances of the case, Dr. Macdonald resolved to temporise—holding everything in readiness in case of need—and endeavoured to improve the general health by administering quinine and iron, with the application of cold and the usual styptics locally, suitable diet and regulation of the bowels &c. Before resorting to more active measures it was decided to give a trial to Kosobudki's modification of Unna's treatment by chrysarobin; accordingly the following formula from Whitla's "Dictionary of Treatment" was employed: One grain of chrysarobin, a quarter of a grain of iodoform, an eighth of a grain of extract of belladonna, thirty grains of cocoa butter, with a sufficiency of glycerine to form a suppository, one to be introduced daily. One was inserted on July 15th and the treatment continued daily until the 31st, when a large slough came away, followed by a little hæmorrhage, since which date he has been practically cured. During the treatment there was a little hæmorrhage on several occasions, but since the removal of the slough there has not been the slightest sign of hæmorrhage, pain or protrusion, and as far as can be seen the result is most satisfactory, even if the cure does not turn out to be permanent. No pain or discomfort was felt throughout, neither did the patient lie up entirely. He was allowed to sit up every afternoon, and, with the exception of a dose of compound liquorice powder every other night, no other treatment was considered necessary beyond what has already been stated, and he is now going about as well as he was before the attack came on, and is likely to continue so, regulation of the bowels being the only precaution practised.

## Medical Societies.

### MEDICAL SOCIETY OF LONDON.

#### Presidential Address.

THE opening meeting of the Medical Society of London was held on Oct. 17th, the President, Mr. Jonathan Hutchinson, in the chair.

THE PRESIDENT delivered an address on Names, Definitions, and Classifications in Disease, of which the following is an abstract:—

"I propose, with your permission, to avail myself of your President's chair in order to make a few suggestions and criticisms in reference to a topic of great importance, and at the same time of much difficulty. I allude to the necessity, which is probably felt by most investigators, for a large reform in medical nomenclature, for better classification of disease, and, above all, for more precise definitions of the terms which we use. We have outgrown the nomenclature of our forefathers and it would be strange if it were not so. If the few and simple names which sufficed to express the diagnostic achievements of a century ago were sufficient for us now the fact would imply disgrace. For the multifarious manifestations of the results of the innumerable influences which combine together to evoke disease in man our names are, I cannot but think, in ludicrous disproportion to our needs. Though there exists an intense dislike, which to some extent is well based, to the introduction of new names, and especially to attempts at new classification, yet, having regard to the future progress of clinical knowledge, I here make my most earnest protest against the present restriction of our nomenclature and the artificiality of our classifications. Let us not for one moment underrate the importance of the everyday achievements of ordinary diagnosis, or of that common knowledge of common things which is a *sine quâ non* to all of us. Our concern is rather to assert strongly that so soon as the specialist attempts to transcend his specialism; as soon as the physician or surgeon tries to get out of routine and makes the attempt to understand not alone some but all the problems of pathogenesis which are brought before him, so soon will each and all find themselves cramped and hindered by our narrow and conventional system of nomenclature and our fragmentary classifications. I ask the neurologist whether such names as 'tabes dorsalis' and 'epilepsy' do not now each include a number of separate maladies which require separate grouping. I ask the physician whether he is content with the terms 'diabetes' and 'hysteria;' whilst, respecting dermatology, I venture to offer my own opinion that there are at least twenty maladies classed under the name of 'lupus' which require to be discriminated, and,

putting all these aside, some five or six different types of tuberculosis of the skin. But nothing can be more obvious than that names, definitions and classifications are far more difficult in our department of natural observation than in any other. Such words as 'species' and 'genus' in our special pursuits are terms having only an exceedingly restricted use. The more we know the less we are inclined to admit respecting any given disease that it is substantive and self-complete; but the fact that definitions and classifications are in the case of medical pursuits immeasurably more difficult than in most other branches of knowledge does not make them of any the less importance. An orderly arrangement of the materials before us is the first requisite to success in the pursuit of further discoveries, and just as an adequate vocabulary must of necessity precede the making of definitions, so must carefully studied definitions precede any attempt at classification which will not necessarily result in error. Whilst in a progressive science like ours stereotyped definitions and fixed laws of classification are impossible, I yet protest against that idleness of mind which is content to go on using words to which no definite meanings have ever been assigned and to abstain from attempts at natural classification merely because such classification is difficult. A distinction must be drawn between a description and a definition. A good description should neglect nothing which may help to identification and is not a difficult achievement to any good observer, whereas a definition may be very good, yet from the fact that it concerns itself rather with abstract qualities may give but little immediate aid towards the recognition of the thing defined; to formulate it demands much thought as well as observation. In order to illustrate what I have been trying to urge we will take the names of three common diseases—phagedæna, erysipelas and diphtheria—and try to define them, and at the same time show how their definitions affect their position in any system of classification founded on natural affinities. Respecting phagedæna, it may perhaps be said that it is not the name for a disease, but rather for a certain condition occasionally assumed by the inflammatory process. I will assume that between simple phagedæna, sloughing phagedæna and hospital gangrene there is no difference of kind, but only of degree of severity; that hospital gangrene is simple phagedæna having become epidemic in a hospital containing patients affected with wounds. I assume also that the gangrenous affections which attack the mouths and genitals of young children, and which are known as noma and cancrum oris, are really of a closely similar nature, though of a more severe type, with the phagedæna which we so often encounter in syphilis. These data being granted, we have first to note that it is undoubted that cancrum oris, noma and syphilitic phagedæna may begin quite independently of contagion. It is therefore not a specific malady in the sense of being dependent upon the implantation of a specific virus. Next we must record that, although these inflammations may occur to persons seemingly in robust health, they are almost invariably those who have suffered from syphilis or, in the case of noma and its congener, recently passed through a specific fever, measles, variola or whooping-cough. With somewhat more hesitation another assertion may be made—that the use of mercury has often preceded, not only the syphilitic forms, but also those seen in children. We come, then, to the definition of phagedæna as a locally destructive form of inflammation which attacks sores and wounds, which varies much in severity in different cases and which occurs for the most part in those who have recently suffered from some specific disease. To this must be added the important proposition that, although capable of a spontaneous origin under the conditions mentioned, it is infective to adjacent parts and may become contagious to other patients with open wounds. We abstain from any description of a phagedænic wound, for the appearances may differ very widely in different cases. For classification purposes we have enough. Phagedæna is not to rank with the specific fevers, although it may become epidemic; it is a type-form of specialised inflammation occurring under certain known conditions of predisposition. The term 'erysipelas' is suggestive of controversy. For long there have been two schools of opinion—the one regarding it as a specific fever and classing it with the exanthems, the other ranking it only as a specialised form of inflammation. The difference is very important. I am glad to observe that the philosophic Dr. Hirsch has ranged himself with the latter, and defined erysipelas as 'an infective inflammation-disease of the skin or of one of the mucous mem-

branes &c.,' and speaks of 'the infective fever which accompanies the local process.' On the other hand, most recent English authorities prefer to regard it as an exanthem. The facts which oppose this claim appear to my mind to be definite and conclusive. When erysipelas attacks a wound its development is always local, and the constitutional disturbance is in ratio with the extent of surface involved. It may develop without any appreciable incubation stage, and it may be cut short at any period by suitable local treatment. Its duration is not uniform, but may be indefinitely protracted. One attack does not prevent a second, but, on the contrary, predisposes to others. Thus, then, I come easily to the conclusion that erysipelas is a name for a form of inflammation presenting peculiar features, very infectious to the tissues—the lymph spaces of the patient—easily spreading by contagion to the wounds of others, and of which one attack leaves proclivity to a second. We have to add to this, however—unless, in contradiction of all probability, we insist that medical and traumatic erysipelas are two quite different things—that it is capable of origin from exposure to cold and without either wound or contagion. Erysipelas is, it will be seen, placed according to this definition by the side of phagedæna, and just as it would be more correct to speak of phagedænic inflammation rather than of phagedæna, so it would be better to use the expression 'erysipelatos inflammation' rather than erysipelas, since the latter is too suggestive of a substantive disease which always runs the same course and always presents the same conditions. Let us now see how the case stands with diphtheria. It is interesting to note that this name has been substituted for what was not improbably a far more correct one—diphtheritis. What is there to hinder us from defining this affection as a contagious inflammation of the mucous surfaces, and chiefly of the throat, frequently attended by the formation of pellicles, infective by continuity in the patient and easily spreading by contagion to others? It would surely be wrong to make the formation of the diphtheritic false membrane a part of the definition, for when the disease passes by contagion through a household there are always some cases which show very little membrane and often a few in which there is none at all. We do violence to probable truth if we deny that these latter are diphtheritic cases, for they originate from contagion from those which undoubtedly are such. The medical officers of those metropolitan asylums which receive fever and diphtheria cases always in their reports count a certain number of cases sent to them as 'errors in diagnosis,' and of these a considerable number are 'non-specific sore-throats' sent in as diphtheria. This is surely rather hard upon those who send them. It is to make the diagnosis of disease depend not upon its origin, but upon the degree of severity with which it develops certain peculiar phenomena which are common but not invariable. No man attending a number of patients with sore-throats, in a house with diphtheria, can possibly tell which will develop extensive membrane and which may have none. There are other important facts which ought to be taken into consideration in the definition of diphtheria. It is quite impossible to distinguish the sporadic cases of membranous croup from those of epidemic diphtheria; and admitting, as I think we must, that they are exactly the same, we are almost forced to conclude that a disease which becomes contagious may originate independently of contagion and in connexion with exposure to cold and damp. In these points the facts as to diphtheria are exactly parallel with those as to erysipelas and phagedæna. All three occur sporadically and in connexion with individual proclivity rather than specific influences, yet all may become contagious, may prevail as epidemics, and when they do so keep close to the type. I have ventured to attempt explanations of these three words, not with any object of giving model definitions, far less with any hope that what I have expressed will satisfy others, but rather to illustrate the importance of the matter and the lines upon which I think we ought to proceed. I feel sure that I shall incur criticism for not admitting to a foremost place in the definition of such affections as diphtheria and erysipelatos inflammation the parasitic microbes which have been demonstrated to be usually present. Whilst I fully admit the importance of the facts which have been established in respect to them, and think that it is highly probable that they do take a large share in the process of contagion, I am not yet convinced that they constitute the disease. It may be one thing that these parasites should be capable of conveying the disease and another that it should invariably depend for its origin

upon their implantation. In the same way the precise rôle of the bacillus of leprosy is, I think, far from being as yet established, whilst it would certainly be very premature to define any one form of lupus as the product of the bacillus of tubercle. In other maladies, such as rhinoscleroma, the presence of a microbe has been demonstrated in only a few instances, and to this and to others in which the search for a parasite has up to the present been fruitless I think that the disease, which is well characterised, should take its name independently of them. It is mainly in reference to very rare maladies that the invention of new names is required. For their illustrative value they are of extreme importance and ought as promptly as possible to become objects of general knowledge. In the same way the varieties of well-known diseases are worthy of recognised distinctive names. It becomes therefore of much importance to find out the most convenient method of giving names, what kind of names are the easiest to use and to remember and the least liable to suggest error. With regard to those supposed to be derived from Greek roots and to be more or less descriptive, we may object that they are intelligible only to Greek scholars, and not always to them; that to all others they are very unattractive, as, in addition to their being meaningless, they may possibly be difficult to remember and a little uncertain as to pronunciation and orthography, and principally because it is impossible to condense into Greek words, however composite, anything approaching to a correct description of a disease. Another class of names is that in which the name of the observer is affixed to the morbid phenomena observed; but it has the obvious objection that it cannot be indefinitely or even widely adopted. If, then, we revert to the proposition that names for new diseases or new varieties or combinations of symptoms should be selected solely with a view to the convenience of the profession, a few simple rules may, I think, be laid down. Such names should be short and easily remembered; they should be in the vernacular; they should be available from the very beginning, and such as the observer himself may without indecorum apply; and they should have in themselves no meaning, the reader being left to find that out by reference to the writings of the observer who first named them. I myself have long been in the habit of naming diseases which were new to me after the patients who first displayed them. It is a subject upon which I have thought much, and respecting which I have some little experience, and seriously I have no better suggestion to make to the systematic case-collector than that he should at any rate temporarily designate what appear to him to be novelties by the names of the patients displaying them. The present plan of trying to make a small number of names suffice for a vast variety of objects and of slavishly grouping together, because our fathers did it, under one and the same name diseases which differ widely is one which has encumbered us too long. Probably there is no better plan in aid of exactitude in clinical observation than to take type-cases, to follow them to their end, describe them in detail, and, wherever possible, to illustrate them by photography or drawings. By the side of the type-case place all others which really fit with it and none else. I have often thought that in such a subject as dermatology it might be well to throw aside all our names and take simply good, well-illustrated case-narratives, and sort them afresh. We should escape in this way the trammels which education has imposed and we should see natural differences and resemblances which at present elude us. I have left myself but little time to deal with the topic of classification, which I know well is a *bête noire* with many. It is supposed that the state of our knowledge does not as yet permit it. Let us remember the enormous gain to botanical science which resulted from the substitution of the natural system for that of Linnæus. Diseases of the skin have perhaps been classified with more elaboration than any other, yet not only has no really natural grouping been attempted, but the arbitrary classes and orders which have been arranged cannot, I think, be said to afford to the student anything approaching the amount of assistance which the scheme of Linnæus, artificial as it was, undoubtedly gave to the young botanist. Yet is it not possible to attempt something in the way of a natural classification of skin diseases which should be of the utmost value to the student? And what is possible in dermatology might be attempted in general medicine. He who would classify with success must enter upon his task with courage. He must not be afraid of details, he must

resolutely eschew all pedantry, and be determined that nothing shall induce him to put two things in the same family group unless he is sure of their relationship. He must be willing to forgo the hope of completeness and think but very lightly of finality. Under these conditions I certainly believe that a very useful classification of skin disorders according to natural affinities is both desirable and possible. We could not assign at once all maladies to their proper places, but this is not requisite. What is wanted is to effect such an orderly arrangement of classes and groups that when once the real nature of a disease is recognised there is a place for its reception. I would take a hint from botanists and name the several orders after their most prominent and typical example. Thus the disease known as 'psoriasis' having been carefully defined, I would place with it in a psoriasis family all forms of skin diseases which conform to similar laws. So with acne, pemphigus and many others. Perfectly natural groups might be formed of those caused by animal parasites and of those due to cryptogamic growths. Other groups might be constituted by those due to congenital peculiarity of tissue (Kaposi's malady and the like). In every case real affinities—in other words, relationship by sameness of cause—should be the guide in the formation of our family groups. In conclusion, I can only hope that the topics I have been bold to bring before you have not seemed to you unsuitable for the first meeting of a new session of the Medical Society of London."

#### CLINICAL SOCIETY OF LONDON.

*Intestinal Obstruction accompanied by Thrombus in the Abdominal Aorta extending down the Iliac Vessels.—Extensive Nævus of Peritoneum.—Traumatic External Iliac Aneurysm in a Boy.—Cicatricial Stricture of Œsophagus treated by Complete Division.*

THE first ordinary meeting of this Society for the winter session was held on Oct. 14th, the President, Sir Dyce Duckworth, being in the chair. The President first addressed a few words of welcome to the members on reassembling after the vacation.

MR. W. H. BROWN of Leeds read the details of a case of Intestinal Obstruction accompanied by Thrombus in the Abdominal Aorta extending down the Iliac Vessels. A man aged fifty-eight, previously healthy, was seized with sudden pain in the body; the usual symptoms of obstruction followed, but were never severe, and entirely subsided before death, which took place seven days later, the cause of death being gangrene of both lower limbs. The post-mortem examination showed a band enclosing five feet of small intestine in a gangrenous condition, together with a clot (thrombus) in the abdominal aorta plugging the vessel from just above the bifurcation to the termination of the iliac vessels.—The PRESIDENT regarded the thrombosis of the aorta as coincidental rather than consecutive. He asked if the omental adhesion acted as a band and compressed the intestines, thus causing the gangrene.—DR. GLOVER inquired for further details as to the previous history.—MR. BROWN, in reply, said the omental adhesion had acted as a band and constricted the intestines. It was not attached to the aorta. The mesenteric vessels were very fully laid open, but contained no clot. There was no previous history of illness or syphilis.

MR. ARBUTHNOT LANE related an instance of Extensive Nævus of Peritoneum. The boy, aged seven, was said to have had a tumour in the right side of the abdomen at birth, which increased rapidly with the growth of the child, till it attained a considerable size. It fluctuated in parts, was apparently situated beneath the abdominal muscles and was not free in the abdominal cavity. The skin covering it was normal. The bulk could not be affected by pressure, nor could it be displaced from its position in the right side of the abdomen. As it extended to the umbilicus it was impossible to determine the condition of the kidney or its relationship to the tumour. Mr. Lane cut down on the tumour, which proved to be navoid, containing large cysts filled with fluid blood. It extended backwards over the peritoneum, to which it was inseparably connected, and from which it apparently grew over the surface of the kidney and beneath the diaphragm over the liver, and in front to the middle line, at which limits it terminated gradually by becoming thin. It was thickest about the centre. It infiltrated somewhat the abdominal muscles which covered it. The peritoneal cavity

was opened, when its inner aspect was seen to be livid and to present rounded masses, some of which were partly pedunculated. All of the growth which could be got at was removed, only a thin layer being left on the outer surface of the peritoneum. The child became entirely collapsed from the considerable loss of blood consequent upon this part of the operation, its pulse becoming extremely feeble and about 170 a minute. This collapse was at once removed by the introduction into the circulation of a pint and a quarter of normal saline solution. The lad recovered without a bad symptom and now presented no sign of any recurrence of the tumour. The growth proved to be nœvoid in structure.—Mr. SURTON inquired if the growth was really a nœvus, or if it was a very vascular nœvo-lipoma. Lipomata were common in the subperitoneal tissue?—Mr. EVE had recently operated on a nœvus of similar character at the London Hospital. It occurred in a young girl of sixteen, and involved the thigh near the knee. The history was indefinite and it was regarded at first as an encysted abscess in the knee-joint. An exploratory incision showed the tumour to be deep-seated, and on opening it there was a great gush of blood. It consisted of numerous cysts filled with blood connected by tissue of a spongy nœvoid structure. It had spread into the muscles and had extended into the knee-joint, involving the deeper layer of the synovial membrane. The tumour extended upwards nearly to the junction of the upper with the middle third of the thigh. He removed it and the patient recovered without a bad symptom. He regarded the growth as a nœvus, but would not be surprised if it contained sarcomatous structure.—Mr. BARKER asked if there were signs of lymphatic structure in the growth. He assisted Mr. Marshall to amputate the thigh for an enormous nœvus in a child, and in this growth the lymphatics were as much involved as the veins.—Mr. GOULD inquired how great an extent of peritoneum was removed.—Mr. LANE, in reply, said that the growth contained no fatty tissue. He snipped off many grape-like masses which projected into the abdominal cavity, but left the intervening peritoneum which was covered with nœvoid structure. There was no evidence of lymphatic enlargement.

Mr. CLUTTON read a paper on a case of Traumatic Aneurysm of the External Iliac Artery in a boy six years of age. On May 24th, 1891, Mr. Clutton was summoned by Messrs. Pitts and Holland of Chelmsford to see a case which they stated was a traumatic aneurysm of the external iliac artery. A boy, aged five years and a half, on April 29th, was presented with a pocket-knife, and in cutting some cake ran it into his abdomen. Mr. Pitts found a small punctured wound an inch and a half wide above the centre of Poupart's ligament. There was very little external bleeding, but a rounded deep-seated swelling could be felt beneath the wound. The next day emphysematous crackling could be detected for about eight inches around the wound, but no increase of the deeper swelling. On May 4th the swelling was first felt to pulsate, and at the same time a bruit was heard extending from this spot down to the femoral cavity. At the consultation on May 24th it was agreed there was an aneurysm of the external iliac artery above the origin of the epigastric. As there were no urgent symptoms it was thought best to wait for a few weeks in the hope of improving the collateral circulation. On June 15th the aneurysm was exposed and a kangaroo tendon applied to the external iliac artery immediately above the aneurysm. A similar ligature was also applied to the external iliac artery below the aneurysm, which was thus completely cut off from the circulation. The wound healed rapidly and the case made an uninterrupted recovery. There was no return of pulsation, no sign of gangrene, and the boy was now perfectly well. A small hard lump could be felt in the position of the original aneurysm and the pulsation of the femoral artery below Poupart's ligament was not so distinct as on the opposite side of the body.—Mr. W. H. BROWN had recently tied the external iliac artery from the front and found it very difficult to reach. He asked Mr. Clutton how it was that he first opened the peritoneum and then eventually tied the artery behind it.—Mr. CLUTTON, in reply, said that owing to the thinness of the child he found so little tissue intervening between the peritoneum and the vessel that he preferred before trying to strip up the membrane from the artery.

Mr. EVE brought forward a case of Cicatricial Stricture of the Oesophagus in which œsophagotomy was performed for removal of an impacted Symonds' tube and the stricture completely divided; there was no recurrence two years after the operation. The patient, a girl aged seventeen, came

under his care in July, 1889, for a stricture of the œsophagus which resulted from swallowing some nitric acid twenty months previously. During this period she had been repeatedly treated by passage of bougies with constant recurrence of stricture. This was low down in the neck and admitted a No. 11 bougie. For the purpose of facilitating feeding and keeping up continuous dilatation a No. 7 Symonds' tube was passed and left in. On July 29th this was replaced by a No. 11 tube quite new. On July 31st the house surgeon, in attempting to remove the tube, pushed away the thread attached to it, leaving the tube impacted in the stricture. A prolonged and unsuccessful attempt to seize the tube with forceps having been made the same afternoon, œsophagotomy was performed on the left side on Aug. 3rd. The operation was performed as low as possible, but after incising the œsophagus it had to be drawn up with forceps before the tube could be reached and extracted. By still further drawing up the œsophagus the narrowed part was completely divided with scissors. The wound in the gullet was closed with sutures, but the internal wound was left open. The patient made a good recovery. She disappeared on Nov. 16th, and was not seen again till Nov., 1891, when she called at the hospital in answer to a letter from Mr. Eve. At this time, more than two years after the operation, she stated that she had been quite well in the interval and had no difficulty in swallowing whatever, a No. 18 bougie passed rapidly encountering no obstruction. He drew attention to the fact that the stricture was an exceedingly obstinate and resilient one before the operation, which might be claimed to have effected a permanent cure. The operation might be compared to external urethrotomy for stricture, but the tendency to recontraction appeared to be less in the case of the œsophagus than of the urethra. During the operation he was surprised at the mobility of the œsophagus in the direction of its long axis. This allowed of division of strictures very low in the neck, even impinging in the upper part of the thorax. After referring to the relative mortality of œsophagotomy and gastrostomy he pointed out that in cases of stricture of the œsophagus in the neck in which gastrostomy would otherwise be indicated, œsophagotomy fulfilled the same purpose, admitted of complete cure by division of stricture and was less fatal. Oesophagotomy might also be sometimes indicated in less severe cases of resilient stricture which had resisted other methods of treatment.—Mr. CLUTTON alluded to a case which he had recorded last session of a fibrous stricture in a child which had been treated by œsophagotomy, and in which, though he added much to the risk of the patient, he could not get the stricture up to the wound nor could he pass anything through it, being obliged in the end to do gastrostomy. He was inclined to think that œsophagotomy would not be of general use in this class of case.—Mr. MAKINS referred to a case of permeable stricture of the œsophagus in which it was difficult to pass bougies. It was treated by rapid dilatation by means of an instrument devised for the purpose much like that of Holt's for splitting urethral strictures. The result was strikingly successful.—Mr. EVE, in reply, said Mr. Clutton's case was not a parallel one because the stricture was not in the neck, but in the thorax. In cases of stricture at the lower part of the neck the result of this operation would be speculative. In the case he related the stricture was so resilient that he doubted if dilatation by any method would have been productive of permanent cure.

#### PATHOLOGICAL SOCIETY OF LONDON.

*Myxœdema treated by injections of thyroid juice.*—*"Fat necrosis" associated with disease of the pancreas.*—*Con genital cystic disease of the scrotum.*—*Hepatic cirrhosis from cardiac valvular disease.*—*Unstriped myoma of penis.*—*Fibrous plaque from penis.*—*Specimens illustrating parasites of malignant disease.*

THE first ordinary meeting of the Pathological Society for the present session was held on Oct. 18th, the president, Sir George Humphry, being in the chair.

Mr. HURRY FENWICK showed two female patients who had been suffering from Myxœdema and who had been treated by injections of fresh thyroid juice. Both had improved and in both the injections had been followed by a gradual increase in the daily average of urine passed. Usually there was a large increase in the urine the day

following the injection; the amount then fell, but rose again. The character of this extra urine was essentially nervous in type. There was often a remarkable increase on excitement, such as the visiting of friends, and also during the period of menstruation, and these variations introduced fallacies into the investigation as to how far the injection acted as a diuretic. Control injections of water were without result; also in healthy people the thyroid juice usually proved negative. Mr. Fenwick, after reviewing the details of the cases, was inclined to believe that thyroid juice had feeble diuretic action; that the *rationale* of its renal action in myxœdema was the change it produced in the blood which permitted of an easier transudation of secretion by the kidneys. He founded the latter supposition on the very marked effect which the injections made in the growth of the hair, the secretion of sweat and the catamenial period. The tables of daily urine seemed to favour Mr. Fenwick's belief that congestion of the kidney arose in congestion of the pelvic viscera such as obtains in menstruation, coition &c.—The PRESIDENT asked the author if he believed that the improvement was due to mucin being passed by the kidney.—Dr. HADDEN said that during the summer he had injected two cases of myxœdema with thyroid juice, and the condition of urine which had been described did not exist in these cases. As regarded the existence of mucin in the urine, many cases had been analysed and no excess of mucin had been found in the tissues.—Dr. ARMAND RUFFER referred to two cases he had seen in Paris which had been injected; in neither was there any change in the urine, but they both suffered from intense headache as a result of injection. One was a young woman twenty-five years of age, who three months after the first injection was practically cured. The second case was an older woman, and the result of the treatment was also a striking therapeutic success.—Dr. A. MORISON said he had seen similar great benefit follow systematic massage; the urine increased and the patient improved for a time, but ultimately the massage lost its apparent effect and a fatal result ensued.

Dr. H. D. ROLLESTON showed specimens of "Fat Necrosis" in the fat of the mesentery, the great omentum, and in the appendices epiploicæ. The areas of necrosed fat were of an opaque white colour; in size they varied from a pin's head to half a split pea; in shape they were round or oval. They were not raised above the surface and were not surrounded by an area of congestion. The contents of these opaque spots gave the reactions of fat. Microscopically the areas were composed of fat cells distended with granular material, which was in places crystalline; the nuclei of the cells did not stain; these areas were immediately surrounded by normal fat cells; some of these areas of fat necrosis showed some small cell proliferation at their margin, but usually on one side only, and near a small vessel. The specimens were taken from two cases under Dr. Cavafy's care in St. George's Hospital; the first case was chronic, the second very acute. In the first case a woman aged fifty received a blow on the abdomen, which was followed at once by pain and the next day by severe vomiting, inaction of the bowels and collapse, simulating intestinal obstruction. The vomiting continued and slight diarrhœa came on. An abscess developed in the right hypochondrium three weeks and a half before death, which took place eighty days after the injury. Post mortem there was found an abscess in the head of the pancreas and fat necrosis in the subperitoneal fat. The liver was in a condition of fatty infiltration, but there was no necrosis of the fat globules. In the second case a man thirty years of age had suffered from an injury to his abdomen eighteen months previously, by a cart passing over him. Since then he had had severe attacks of abdominal pain. After his dinner he was suddenly seized with abdominal pain, vomiting and collapse, accompanied by constipation. Laparotomy was performed, and death occurred thirty-six hours afterwards. At the necropsy hæmorrhage was found round the pancreas, the origin of which was not manifest. There was disseminated fat necrosis in the abdomen, but there was no evidence of pancreatitis. In neither case was there any fat necrosis in the fat of the thighs or of the abdominal wall. The author said that there were two theories: (1) That the fat necrosis was a primary change in the fat of the fat cells, which set up a surrounding inflammation, which, becoming confluent around the pancreas, produced changes in, and often ultimately necrosis of, that organ (Langerhans). (2) That pancreatitis, hæmorrhagic, suppurative or gangrenous, or pancreatic hæmorrhage was the primary lesion which by extension produced fat necrosis (Fitz). Dr. Rolleston said that neither of these hypo-

theses was very satisfactory, and that he thought that the occurrence of fat necrosis might be explained as a trophic lesion, the result of the morbid process spreading from the pancreas to the solar plexus. This view was supported by the clinical symptoms, which were those of great disturbance of the sympathetic (vomiting, collapse and constipation), and the distribution of the fat necrosis would fit in with this view.—Professor ADAMI said that this disease was not necessarily associated with inflammation, and in the instances related he could confirm this from an examination of the author's specimens. Any small cells which were present near the necrosed areas were to be accounted for by the action of the fat necrosis as a foreign body. In the acuter case he thought that the fat necrosis was primary, and had existed before the lesion of the pancreas. He agreed that the nature of the change was probably nervous and trophic.—Dr. HALE WHITE said that hæmorrhage in the neighbourhood of the pancreas was rare. He asked for fuller clinical details of the case, and inquired as to the state of the intestines. These cases had been more than once mistaken for intestinal obstruction.—Dr. ROLLESTON, in reply, said that in neither case was there intestinal obstruction. In both there were some peritoneal adhesions, but they did not compress the gut.

Mr. EDGAR WILLETT showed two Congenital Cystic Tumours of the Scrotum. In each case the tumour was removed from the scrotum of a boy; the testis, though lying adjacent, was not adherent or affected; their pathology remained obscure. Microscopical sections were also shown.—Mr. TARGETT said that Mr. EVE had formerly shown a somewhat similar specimen as a dilatation of the ducts in connexion with the organ of Giralddès. It was from a boy aged seven, was congenital and consisted of a mass of fibrous tissue containing smooth-walled cysts. Another similar case he had recently seen in a child aged five. He regarded them as degenerated nævi, for the cysts had no epithelial lining and some of them contained blood-clot.—Mr. BOWLBY had seen similar specimens both in the scrotum and in Nuck's canal in the female. He believed that they were not congenital nævi; the material obtained from the cysts was a clear serous fluid. They were precisely similar both to the naked eye and microscopically to the growths often found in the neck.—Dr. NORMAN DALTON said that some years ago he had examined one of the congenital tumours of the neck by staining it in the recent state with nitrate of silver. He then found that the lining of the spaces was of epithelioid character, such as that which might be found lining an old nævus or a lymphatic cyst.—Mr. WILLETT, in reply, said that the cysts in these cases were quite separate from each other, which he thought would not be the case if it were a degenerated nævus.

Dr. PERCY KIDD showed specimens of Cirrhosis of the Liver, Pancreas and Kidney from Obstructive Valvular Disease of the Heart. He said it was a case of severe long-standing valvular disease of the heart, with enlargement of the liver, terminating with anasarca, ascites and hydrothorax. At the necropsy it was found that the liver was enlarged and very hard, but smooth on the surface. The hepatic veins were dilated and thickened. The heart showed an extreme degree of stenosis of all four valvular orifices, and was greatly hypertrophied and dilated. The pancreas and kidneys were also greatly indurated. Microscopical examination disclosed undoubted cirrhosis of the liver, pancreas and kidney. The etiology of the case was discussed and reasons were given for attributing the cirrhotic change in these organs to the extreme degree of cardiac obstruction. No evidence of alcoholism could be obtained. The lungs were in a condition of brown induration.

Mr. SHATTOCK showed for Mr. Sydney Jones an Unstripped Myoma of the Penis. There was a thickening of the fibrous investment of the corpus cavernosum, with a small gritty plate lying in its centre. This he had carefully analysed to see if it were of gouty nature, but it contained no trace of uric acid and was composed of phosphate of magnesium and lime. Beneath the fibrous thickening there was a remarkable increase in the involuntary muscle fibre of the trabeculae. There was nothing in the history of the case to give a clue as to its nature. There was no history of syphilis or of gout.

Mr. EDGAR WILLETT showed a Small Calcareous Plaque which had been removed from beneath the skin of the dorsum of the penis of an elderly gentleman. It apparently arose in a part of the fibrous tunic of the penis. It had been noticed for two years and a half, and its substance was, as in the preceding case, mainly composed of unstripped muscle fibre.

Dr. HEBB showed some specimens illustrating the parasites of malignant disease. They were taken from the body of a

young man twenty-six years of age, who died of ascites and jaundice. There was found a diffuse subperitoneal fibrosis, and there was the scar of an old ulcer an inch or so from the cardiac end of the stomach on the lesser curvature. A microscopical examination of the subperitoneal fibrous inflammatory deposit showed it to contain giant cells, which were for the most part mono-nucleated and contained spheroidal bodies. In the centre of each was an aggregation of granular matter and from these granules lines, also granular, radiated to the periphery. In other specimens the spheroidal bodies were larger, with a circular centre like a nucleus, but with granular contents. These bodies had a distinct capsule and they stained quite differently from a tissue nucleus. He showed them as specimens occurring quite independently of malignant disease, but in an ordinary chronic inflammatory growth. He had stained them according to the method recommended by Dr. Russell two years ago.

The following card specimens were shown:—

Dr. PEROY KIDD: Embolic Aneurysm of the Pulmonary Artery.

Dr. E. C. PERRY: (1) Perforating Ulcer of the Duodenum; (2) Fatal Intra-pleural Hæmorrhage in Pneumonia.

## Notices of Books.

*The Journal of Pathology and Bacteriology.* No. 2. October, 1892. Edinburgh and London: Young J. Pentland.—The second number of this new and high-class periodical contains matter of even more interest than the first, and well justifies the undertaking. Dr. R. Muir of the University of Edinburgh contributes a paper on Leucocythæmia, consisting of a careful study of the blood by modern methods. His observations tend to the conclusion that the changes in this disease depend on an "excessive and indefinite proliferation of a certain kind of cell," but he abstains from constructing any more definite hypothesis until he has had further opportunity for the study of the subject. Mr. A. A. Kanthack of Cambridge University writes on Madura Disease (Mycetoma) and Actinomycosis, in which he clearly establishes the identity between them—an identity suspected by Vandyke Carter, to whom is owing much of our knowledge of the pathology of mycetoma. Mr. Rubert Boyce of University College, London, describes the characters of an example of Aspergillæ Pneumonocystis which occurred in a subject of cardiac disease, and to the unaided eye resembled small white bodies within a few bronchitic cavities at the apex of the lung. Dr. T. Haldane and Mr. J. L. Smith of the University of Oxford contribute a paper of considerable importance upon the Physiological Effects of Air vitiated by Respiration, in which they show that these effects (hyperpnœa, headache &c.) are due mainly to excess of carbonic acid and deficiency of oxygen rather than to any special poison. Dr. Archibald Garrod writes on Hæmatorporphyrin as a Urinary Pigment in Disease, based on an extended examination of a variety of cases. A paper of some elaboration, and embracing a topic of great interest at the present time, is that on some Parasitic Protozoa found in Cancerous Tumours by Drs. Amand Ruffer and T. H. Walker. It opens with a history of previous investigations on the subject, and is itself a most important pathological contribution, which goes far to establish the fact of the parasitic nature of cancer. Dr. Joseph Coats describes the Pathology of Sudamina and Miliaria, in which the histological examination of the skin from a fatal case of rheumatism leads to the conclusion that these states are essentially inflammatory, excited probably by poison excreted in the sweat. Mr. Rubert Boyce and Mr. Cecil F. Beadles describe fully the features, macroscopical and microscopical, of a case of Myxœdema in which there was enlargement of the pituitary body, and their paper as well as the observations of others point to some correlation between the thyroid body and the hypophysis cerebri. The latter, it is well known, is generally found enlarged in

acromegaly. Mr. E. H. Hankin has a paper on the Method of testing the Bacteriocidal Power of Alexin Solutions; and the number closes with a description of Papier-mâché Casts of Pathological Specimens by Mr. C. W. Cathcart, and one on a Rapid Method of Dehydrating Tissues by Mr. G. L. Cheatle. The excellence of the illustrative plates, which are numerous, is very great, and altogether we think that the journal does credit to the British School of Pathology.

*Trattato d'Igiene Publicca.* Del Dottore CARLO RUATA. Vol. I. Citta di Castello. 1892.—We have now so many treatises on public health that Dr. Carlo Ruata's work on the same subject is likely to be less resorted to than it otherwise would have been. But it has qualities of distinct merit which place it amongst the foremost of such works; and if action is taken on the principles which are advocated in it in those countries where the Italian language is spoken the result will be a distinct saving in loss of life due to preventable causes and a greater capacity for remunerative labour amongst those who are spared from the debilitating influence of avoidable sickness. The first volume issued deals with general considerations. It takes up the subjects of vaccination and other preventive inoculations, of the isolation and disinfection called for in infectious disease; and it deals on what we are inclined to regard as very much our English lines—with the question of quarantine. The sanitary cordons in Italy in 1884 are set out as typical of an error of administration. Non-infectious maladies which are affected by public health considerations are next dealt with, as are also questions of vital statistics. The scope and character of sanitary administration generally and of the existing Italian law are next considered, and the volume concludes with some valuable considerations which go to show how public prosperity is dependent on public health. In this and in other parts of the volume Dr. Ruata pays many a compliment to English sanitary work, but he also takes some of his examples of failure from our records. Thus he refers to Dr. Thresh's excellent account of the injurious influence of the bad housing of the population in Ancoats; and since we are involved in that which is bad as well as that which is good, we can the more freely express the opinion that this last chapter should be read by all Italians who are patriotic enough to take interest in the welfare of their country, and since this doubtless includes the whole nation, we trust the volume will have a wide circulation quite beyond professional circles.

*The Sheffield Medical Journal*, Vol. I., Part I. Edited by SIMON SNELL, F.R.C.S. Edin. Sheffield: Pawson and Brailsford.—It speaks well for the pursuit of scientific medicine in this country that the practitioners in so many of our leading provincial towns should be willing to undertake the responsible task of issuing a medical journal. To Bristol, Birmingham, Liverpool and Manchester may now be added Sheffield; and this new journal, which is to be a "Quarterly Review of the Medical Sciences for Yorkshire and adjoining Counties," seems likely to prove a fitting compeer to those above indicated. The general plan of the journal is that followed in most publications of the sort, notably the long-established *American Journal of the Medical Sciences*. Thus it consists in the first place of original articles, next of abstracts and summaries of literary contributions to medicine, surgery and therapeutics, then of reviews and notices of books, new drugs, instruments &c., and medical news. The first article, by the editor, is on Accuracy in Observation and the After History of Cases, being the Presidential Address to the Sheffield Medico-Chirurgical Society, delivered on the 13th inst. Mr. Dale Jones and Dr. Norman Walker relate an Unusual Case of Tuberculosis of the Skin, well illustrated by lithographic reproduction of photographs of the general and histological characters of the case. Dr. W. Dyson describes a well-marked case of Myxœdema in the Male, and another case of Myxœdema, with an account (illus.

trated) of the changes in the thyroid, is contributed by Mr. R. J. Pyc-Smith and Dr. A. J. Hall. Mr. Arthur Jackson, under the heading "Chapters in Local Medical History," commences a description of the history of the Sheffield General Infirmary. The abstracts and summaries are well selected, and the reviews and notices include careful criticisms of such works as Wilson Fox's Treatise and Hack Tuke's Dictionary of Psychological Medicine.

*The Quarterly Journal of Microscopical Science.* Edited by Professors RAY LANKESTER, KLEIN, SEDGWICK and MILNES MARSHALL. No. CXXXIII. August, 1892. London: J. & A. Churchill.—This Part contains the two following Memoirs: 1. The Anatomy of Peritastomum Toretiusculum, a parasite found in the lung of the copper-headed snake (*Hoplocephalus superbis*) of Victoria, by W. Baldwin Spencer, Professor of Biology in the University of Melbourne, with nine plates. 2. The Minute Structure of the Gills of Palæmonetes Varians, by Edgar J. Allan, B.Sc. University College, London, with a plate.

In the September number of the *Annales de l'Institut Pasteur* Messrs. E. Hankin and F. F. Westbrook, in their paper entitled "Sur les Albumoses et les Toxalbumines Sécrétées par la Bacille Charbonneuse," again take up the subject of the albumoses and the toxalbumins secreted by the anthrax bacillus. Following up the experiments of Paternmann, Hankin, Brieger and Fraenkel, and the earlier observations of Sidney Martin, they attempt to bring into harmony the somewhat conflicting results obtained by those various experimenters, and they take up the position formerly held by Martin that there are formed during the growth of the anthrax bacillus, in certain media, albumoses which are not toxic to susceptible animals, but which exert a distinct protective influence against the attacks of the anthrax bacillus, and toxalbumins which possess a distinct toxic power, but have little protective virtue. They found, for instance, that when they produce the albumose directly—that is, by allowing the anthrax bacillus to act on fibrin ferment in bouillon at a low temperature, that such albumose, when injected in small doses into a mouse, confers immunity, but that when they allow a proteolytic ferment to be formed by the anthrax bacillus (this takes place especially at higher temperatures) they cannot obtain any protection; whilst the products that are formed have the toxic action above referred to. They found, moreover, that after separating the albumoses from the purest commercial peptone obtainable that the remaining pure peptone, if acted upon by the anthrax bacillus at a comparatively low temperature, would also yield a protective albumose, though they were not able to obtain it in sufficient quantity or in sufficient activity to produce complete immunity in mice. It is interesting to note that the albumoses do not cause symptoms of poisoning in animals susceptible to anthrax, such as mice, young rabbits and rats &c., whilst it is distinctly poisonous even in small doses to non-susceptible animals, such as frogs and old rats. The results of these experiments are of very great interest, though they go directly against the results obtained by several observers who have found that so long as what may be called the fundamental molecule is present in any series of products the poisonous activity is present, though often necessarily in somewhat varying degree, and it would be expected that similar protective properties would be bound up in this fundamental molecule. However, as the relation of chemical composition to physiological action has not yet been completely or satisfactorily worked out in regard to the better-known poisons, it may be some time before a knowledge of the same relationship is obtained with respect to these complicated albumoses and toxalbumins with which the bacteriologist has to work.

In the October number of the *Veterinarian* Professor Fred. Smith, M.R.C.V.S., F.I.C., of the Army Veterinary School,

Aldershot, continues his article on Veterinary Hygiene, taking up specially ventilation, drainage and individual hygiene, clipping, shoeing and feeding, and concluding this part of his article with the treatment of calves used for the production of vaccine matter. An editorial article on the diagnosis of tubercle by the use of tuberculin leads us to believe that this substance as a diagnostic agent is not so valuable as at one time it was anticipated it might be. Professor Wortley Ayo contributes a paper on "Pleuro-pneumonia: Slaughter justified." An account of the meeting of the veterinary profession held to consider the amendment of the law relating to glanders and farcy is given, together with resolutions adopted and to be forwarded to the Board of Agriculture and the County Council. These recommend amendment and consolidation of the law, immediate and compulsory slaughter, systematic inspection, an increase in the number of veterinary inspectors, compensation and closure of water troughs. The number is completed with accounts of the meetings of the National Veterinary Association, Midland Counties Veterinary Medical Association and South Durham and North Yorkshire Veterinary Medical Association.

*Locke's Annual Register.*—This publication, which the compiler states in his preface will be issued annually, is a work likely to be of use to men of all professions. The work, which is in two volumes, contains, in a convenient form for reference, all notices of births, marriages and deaths advertised throughout the United Kingdom in the leading newspapers. A special feature of the publication is the double indexing of marriages (1) under bride's maiden name and (2) under bridegroom's name. Part II. deals with deaths.

## LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY (LIMITED).

A MEETING of the council of this Society was held on Tuesday, Oct. 4th, and the chair was occupied consecutively by Mr. Bruce Clarke, Mr. Balding, J.P., and Mr. J. Hutchinson. Dr. Cleveland and Mr. Musgrave were elected vice-presidents of the Society. Ninety-eight new members were enrolled.

The following divisions were formally recognised and their respective officers elected—viz., Cornwall: President, Edward Sharp, J.P., M.R.C.S., Truro: hon. secretary, George Frederick Helm, M.A. Cantab., M.D. T.C.D., F.R.C.S. Eng., The Greenfield, Marazion. South London: President, J. W. J. Oswald, M.D. St. And., F.R.C.S. & L.R.C.P. Edin., Kennington-road; hon. secretary, John P. Henry, M.D., B.Ch., L.R.C.P.I., Brook House, High-street, Lewisham, S.E. South-east London: President, Arthur Roper, M.D. St. And., M.R.C.S., Lewisham-hill; hon. secretary, S. Noy Scott, L.R.C.P. Lond., M.R.C.S., Lewisham-hill, S.E. Somerset: President, Thomas Cole, M.D., F.R.C.P. Lond., Bath; hon. secretary, Hugh Lane, L.R.C.P. Edin., The Circus, Bath. Northumberland: President, Walter Ridley, M.S., F.R.C.S. Eng. Newcastle-on-Tyne; hon. secretary, Francis W. Clark, L.R.C.P. Lond., D.P.H. Camb., Dispensary, Newcastle-on-Tyne.

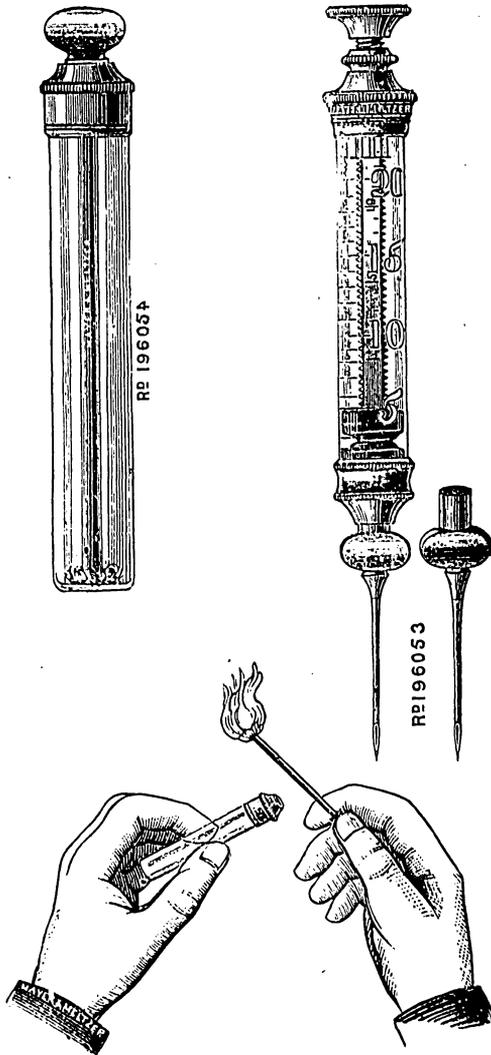

It was unanimously resolved that duly qualified and registered medical ladies should be eligible as members of the Society. The secretaries reported, with regard to the unjust censures of coroners' juries on medical men, that while condemnatory riders to coroners' verdicts were quite irregular, yet it appeared that such statements by coroners' juries were in law regarded as privileged, as also the publication of these in *bona-fide* reports by newspapers. Mr. Balding thought that some legal remedy for the present undesirable state of affairs might be found. It was resolved that Mr. Balding, J.P., and Dr. Cooper Rose, be requested to confer on the subject and to report to a subsequent meeting of the council.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The dinner of the members and friends of this Association is announced to take place at the Holborn Restaurant on Nov. 2nd.

## New Inventions.

### ANTISEPTIC HYPODERMIC SYRINGE.

WE owe to Messrs. Meyer and Meltzer the invention of a hypodermic syringe capable of being thoroughly sterilised after use by the best of all possible means—viz., the application of heat. This is effected by means of a small spirit lamp included in the same case as the syringe, the needle of the latter being removable. The needle is made of an alloy, so that when heated it does not lose its keen point, as happens

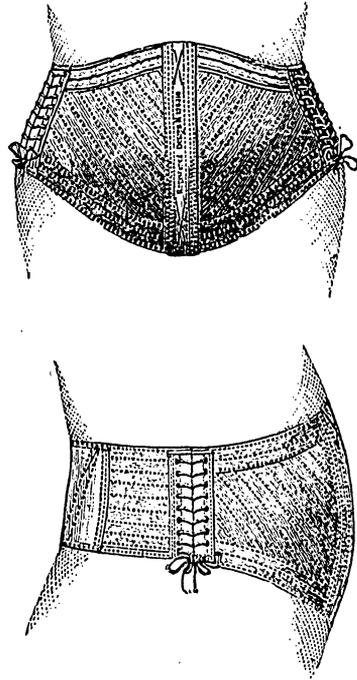

with an ordinary steel needle. Another improvement consists in the needle being of such a shape as to accurately fit the nozzle of the syringe and to be in contact with the piston, thus enabling the quantity injected to be accurately measured. It is needless to emphasise the importance of these instruments being kept perfectly clean and the value as well as simplicity of the means adopted to that end in the present instrument.

### NEW "ORTHONEMIC" ABDOMINAL BELT.

Messrs. SALT AND SONS of Corporation-street, Birmingham, have submitted to us for examination a new form of abdominal belt which they have designated as above, and the construction of which exhibits exceptional features. Two illustrations of the belt are given, a front and a side view. From these it

will be seen that the diagonally arranged front elastic webs (separated by the central whalebone) follow the direction of the external abdominal muscle, and supply the *lifting* support so desirable in these appliances, transmitting the weight of the abdomen to the upper portion of the hips, whence it is distributed by the horizontal side webs equally towards the back, the lacing being also elastic. The transverse top and bottom webs in the front clip the body and retain the belt in

its proper position, thus dispensing with perineal straps which cause so much discomfort. The complicated straps and bands added to most belts to assist their fit are avoided, and the appliance is consequently very simple, the arrangement of the elastic fibres causing it to fit perfectly in every way. The belt appears to be well calculated for increased efficiency, and at the same time an acceptable advance towards simplicity of application.

**VACCINATION GRANT.**—Mr. John P. Balbirnie, L.R.C.P., L.R.C.S. Edin., has been awarded by the Local Government Board a grant of £7 6s., as public vaccinator for the Staveley district of the Kendal Union.

**QUEEN VICTORIA'S JUBILEE INSTITUTE FOR NURSES.**—The report of this institute for 1891 states that the number of nurses trained during the past year and now at work in different places is 19. At the present time there are 27 probationers, 12 of whom are receiving hospital training. Since the commencement of the work 32 nurses have been trained under the institute. The number of nurses under the immediate supervision of the institute in connexion with associations affiliated to it is about 101. The total number of nurses upon the roll is 167, and of these 132 have been added during the past year. Applications are being steadily made to affiliate kindred nursing associations. There are now 32 nursing associations which have been affiliated in England and Wales. All associations are inspected as to their nursing arrangements and the qualifications of the nurses before the request to be affiliated is acceded to, and periodically afterwards. Berkshire, Devonshire, Essex, Gloucestershire, Hampshire, Kent, Norfolk, Somerset, Surrey, Worcestershire and Yorkshire have established associations under the same rules and regulations as the institute. There are in all 34 nurses engaged in rural nursing work in the different counties above named.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 22, 1892.

IN his admirable "History of England in the Eighteenth Century," Mr. LECKY has the following passage:—"Hardly any other of the great branches of human knowledge is at present so backward, tentative and empirical as medicine, and there is not much doubt that the law of supply and demand is a main cause of the defect. Almost all the finer intellects which are devoted to this subject are turned away from independent investigations to the lucrative paths of professional practice; their time is engrossed with cases most of which could be treated quite as well by men of inferior capacity, and they do little or nothing to enlarge the bounds of our knowledge." Criticism from so eminently judicious and moderate a writer as Mr. LECKY is entitled to respectful consideration, even when it trenches on questions outside the range of his own life studies, and we propose to consider how far the above remarks are well founded, and whether any conclusions of value can be drawn from them.

In the historian's view two facts stand out prominently regarding medical science: first, that its progress is unduly slow compared with that of the other great departments of human knowledge; and, secondly, that this slow rate of progress is attributable to the absorption of all the abler intellects in the routine of private practice and their consequent inability to devote sufficient time and effort to original research. Now we do not pretend that the progress of medicine has ever been rapid. It is perhaps the most ancient of the sciences. In all probability, long before primeval man had begun to note with intelligence the movements of the heavenly bodies, or to develop any department of the physical sciences, the hard necessities of a state of constant warfare had compelled the direction of his attention to such subjects as the treatment of wounds and the relief of pain. Botany probably arose partly from the search for articles of food and partly from a desire to discover herbal remedies for disease. Medicine is thus long prehistoric, and its origin is lost in the mists of extreme antiquity. Its progress seems to have followed two main directions: first, that of the theorising school, of whom GALEN is the best ancient representative, whose prevailing characteristic was a desire to bring all the phenomena of disease under a few wide generalisations and far-reaching formulæ; and, secondly, the empirical school, who simply sought remedies for certain ailments without much regard to the *rationale* of their proceedings. Whilst most of the ancient theories about the constitution of the human body and the action of remedies have been proved to be false, experience has shown that some of the ancient empirical rules regarding treatment possess a permanent usefulness and validity. Thus much of the teaching of HIPPOCRATES concerning food, exercise, diet &c. still holds good, even in the light of the most advanced modern knowledge.

This distinction helps to explain what is a most patent but

at first sight somewhat puzzling fact—viz., that the Baconian philosophy and the general adoption of habits of systematised observation and careful induction, which so revolutionised and accelerated the progress of the physical sciences, produced a vastly smaller effect in the field of medical science. Medical science, in fact, owes much more to empirical observation and happy accident than is generally admitted. Such discoveries as the therapeutic virtues of mercury in syphilis or of cinchona in ague probably arose in this way, and it is quite out of our power voluntarily to create that combination of circumstances likely to afford similar fruitful results. The power of creating the special conditions most favourable to observation—of "varying the circumstances," as logicians say—of bringing into play the logical "method of difference" is, in the field of medicine, much restricted. Lack of material in some cases acts as a bar; in others the promptings of humanity restrain us. In fact, the more we reflect upon the subject the more we shall be convinced that any analogy between the progress of medicine and of the physical sciences is wholly illusory. In the first place no science dealing with life can hope to rival in completeness and in rapidity of progress the science of the not-living. A comparison between, say, physiology and mechanics is perfectly futile and wholly un instructive. The mysterious element of life, so subtle, so pervasive, so potent and yet so inscrutable, increases to an altogether incalculable degree the difficulties of observation and induction. When philosophers have determined what life is, what mind is, where the influence of mind or body begins and ends, they will be in a position fairly to reproach with backwardness and slowness of progress a science which has so largely to deal with these difficult questions, and which, amidst the painful exigencies of disease and the claims of suffering humanity, cannot always stop to bring its practice precisely into line with its theories.

The factor of disease adds new and manifold difficulties. If normal physiological life presents much that is perplexing, much more is this true of abnormal and pathological life. Probably no two cases of disease were ever exactly alike. The response of the organism to the imitation of disease always varies, and often within very wide limits. The play of hope and fear, of strength and feebleness of will, of acquiescence in and resistance to medical advice and authority, is never ceasing, and introduces elements of altogether incalculable complexity. We must take our science with its necessary and intrinsic limitations, and, perhaps all things considered, the real wonder is not the slowness of medical progress or the fallibility of medical knowledge, but the almost unerring certainty of insight which is the characteristic of our greatest doctors.

While thus demurring to the principles of comparison implied in Mr. LECKY'S remarks, we are quite in accord with him regarding the necessity of a fair share of the best medical intellect being devoted to the work of original research. Such an end can only be achieved by national endowments or private benevolence. A beginning has no doubt been made in respect of such subjects as anatomy, physiology and pathology, in which chairs of sufficient value exist to enable their occupants to devote themselves entirely to their study. But no chair of medicine, surgery, gynecology or kindred subjects exists with an endowment suffi-

cient to enable its occupant to relinquish private practice and devote himself wholly to original research. It is not too much to hope that the day will come when this gap will be filled up. Many tasks might well be assigned to the occupants of these chairs, such, for example, as the determination of the real practical value of the hosts of new remedies which are now constantly brought under our notice. Most of these are worthless, but it would be a great misfortune to humanity if through lack of sufficient care and thought any really useful additions to our therapeutic armamentarium were thrown aside with the useless.

It is well for medical men to study the diseases of other races than their own. Civilisation is apt to be regarded in these days as not an unmixed blessing, and one of the chief charges brought against it is that it makes us more sensitive and develops many diseases and ailments which our more savage fellow creatures escape. The development of nerves, with all their possibilities of pain and multiplied disorder, is a responsibility especially laid at the door of civilised life with all its luxurious provisions for comfort and enjoyment. Perhaps these ideas are accepted a little too readily. It is certain that we are spared some diseases to which less favoured races are subject. During the course of the session of 1890 of the Clinical Society Dr. STEPHEN MACKENZIE brought to the notice of its members the case of a much-respected native of the Congo who laboured under "negro lethargy," or "sleeping sickness," a disease described by Dr. WINTERBOTTOM and later writers, and which in many villages on the Congo is very fatal, although European races never suffer from it. The non-exemption from sickness and ailment of savage races is illustrated in an interesting way in two papers in the *Medical Record* of New York of Sept. 17th and 24th respectively, by Dr. HOLDER, Assistant Professor of Physiology in the Memphis Medical College and formerly Agency Physician of the Crow Reservation, Montana, of which we may give our readers some account. The severity of eruptive diseases in such backward races has been often shown. The same fact is illustrated by Dr. HOLDER in respect of both small-pox and measles. In 1873 small-pox played sad havoc among some Indian tribes; one-ninth of the Santee Sioux of Nebraska died, and in 1878 over one-fifth of the Mohave and Chimehucvis Indians of Arizona succumbed to the disease. Vaccination has been practised of late years, with the result that no epidemic has raged among any Indian tribe; but they hold small-pox in mortal dread, and a case of it or the report of its occurrence will cause greater consternation and stampede than a hostile invasion. Few tribes are without the traces or its ravages in pitted faces and sightless eyes. Measles is a fatal disease—it is very fatal in some tribes—even when the cases are carefully nursed by the *employés* of the Agency; but much depends on shelter and care. Thus Dr. TRON, of the Crow Creek Agency, in a severe epidemic in 1888 lost 1 in 15 of the cases treated in camp; but of 130 cases treated in the boarding school, where favourable surroundings and good nursing could be procured, not one was lost. Dr. TRON made the curious observation that the stage of incubation was more protracted than among the whites, and that there was a greater tendency to severe capillary bronchitis. In

certain Sioux Reservations in Dakota measles has been shown to be a steady cause of declining population. Epidemics of whooping-cough usually follow measles. Mumps occur frequently, and take a course similar to that among whites, including frequently metastasis to the testicle. Erysipelas occurred in 2065 Indians out of 500,000. Dr. HOLDER'S cases were generally mild, and unconnected with traumatism. In the first cases his attention was drawn to enlarged cervical glands. The next complaint noticed (constipation) is one often thought to be the monopoly of civilised people, living in easy circumstances and pampered ways. Dr. HOLDER finds the Indians universally and persistently constipated; indeed he comes to the conclusion that this is an ailment common to the human family. The Indians do not understand the utility of a medicine which does not either purge or produce vomiting. Like Sir HENRY HOLLAND, Dr. HOLDER moralises on the use and abuse of purgatives. From their wide use he draws the double inference that thorough intestinal evacuations must be beneficial in many different ailments, and that medical men should intelligently combat the enormous abuse of such medicines. The notorious laziness and inertia of the Indian, except under great motives to activity, may account for his constipation, but Dr. HOLDER attributes it partly to diminished animal food and the increased use of bread, made of bolted flour and potatoes, both cooked with grease. He thinks that calomel acts with unusual violence on Indians, though he has often had to give from three to five drops of croton oil to secure a good evacuation. Conjunctivitis is common, and is attributed largely to the smoke of the huts, to the paint applied to the skin and eyelashes by the Indians, and sometimes to the glare of the sun on the snow. Blindness is not common among the Indians, though it results, as we have seen above, from small-pox, as has too often happened in more civilised countries. In fractures, and even compound fractures, the Indian makes a fend for himself with a fracture-box filled with dung, or splints of a plastic clay. In Dr. HOLDER'S experience fractures unite readily, but trivial wounds do not heal by the first intention. Skin diseases are observed, including vitiligo, which is "not rare." Another proof of the amount of "human nature" that there is in Indians is the testimony of Dr. HOLDER and others to the frequency of hysteria among them. They suffer also from epilepsy and hysterical epilepsy; and trance epilepsy is said to be common. Insanity in an acute form is very rare. The teeth of Indians are nearly always perfect, but those of half-breeds are very inferior. Earache and otorrhœa are frequently met with. Valvular heart lesions were found with great frequency among Indian school children. The Indians have the same sense of shame and discredit in contracting venereal disease that more civilised people have, and are in the habit of attributing it to spider bites, though they admit that they never saw the spider. Though so like his fellow creature in most of his complaints, the Indian is generally considered stoical. This is probably due to his having less acute sensation of pain. In spite of this, he is fascinated with anaesthesia. Dr. HOLDER makes some interesting observations on the use of intoxicants. He says he has not the slightest evidence that they are used by any north-west tribe unless supplied by white men—another judgment that fastens on the white races the tremendous responsibility

of alcoholism among savage or barbarous people. Tobacco is not much smoked by the Indian, but smoking, "chiefly of a kind of ground laurel resembling *uva ursi*," is a social and religious ceremony of great importance and interest. The medicine man is rather divested of his medical character by Dr. HOLDER and made to appear as a sort of charmer or magician, being priest or saviour, rather than physician. Even the few that can be called native doctors depend more on the song and the drum than on drugs. They are ignorant even of herbs and are in every way a great hindrance to the success of the Government physician. Still, Dr. HOLDER wisely sees that they can only be superseded gradually and by the Government well supporting efficient men when they find them. Bloodletting is roughly practised, as also a kind of actual cautery with burnt wood. The "sweat house" is an institution in Indian life in which a sort of Turkish bath is extemporised, after which the Indian generally goes out into the snow, with which he rubs himself, and with impunity, even when the temperature is below zero. Here we see a difference which has not been so apparent in the ailments of the races. There is one disease, however, which is conspicuous by its absence in Dr. HOLDER'S Indian nosology—and that is gout.

AMONG other useful measures passed before the close of the last Parliament was that of the Coroners Act. Prior to this becoming law, which it did on June 28th, a deputy coroner could not act after the death of the coroner whose deputy he was, and every borough coroner was obliged to appoint as his deputy a barrister or solicitor. Both these anomalies have been removed by the Act of 1892. It is a short Act, containing only three clauses. The first contains eight sections, and the first section provides that every coroner, whether for a county or a borough, shall appoint by writing under his hand a fit person, approved by the chairman or mayor of the council who appointed the coroner, not being an alderman or councillor of such council, to be his deputy. This, therefore, repeals that clause of the Municipal Corporations Act which limited the appointment to solicitors or barristers, and removes a great injustice to the medical profession. It was manifestly absurd that though a borough coroner might be a medical one his deputy could not. This odious restriction did not obtain in the case of county coroners; but as the larger proportion of these are solicitors it is only natural that they should appoint members of their own profession. We have already noticed a happy exception to this in the case of the late coroner for the Wrexham division of Denbigh, the late Mr. THELWALL, who appointed as his deputy Dr. EDWARD DAVIES, now a candidate for the vacant office. The next two sections provide for necessary formalities which need not be detailed; but the fourth section is very important, since it provides that the deputy of a coroner shall, notwithstanding the coroner vacates his office by death or otherwise, continue in office until a new deputy is appointed, and shall act as the coroner while the office is so vacant in like manner as during the illness of the coroner. It is very marvellous that such a provision was not made long ago. The death of a coroner rendered it necessary for one of the coroners of the adjacent districts to perform his duties in addition to his own, to the

greatest inconvenience of all concerned. In the city of London the Town Clerk had to act. But this was not all the evil resulting from such a condition of matters. The appointment of a new coroner had to be filled up within ten days from the death of his predecessor, which led to hasty and ill-considered elections. This is changed, since the sixth section provides that "a council may postpone the appointment of a coroner to fill a vacancy, either generally or in any particular case, for a period not exceeding three months from the date at which that vacancy occurs." Thus another injustice to the medical profession, will be, it is hoped, removed, as the interval of three months will enable a medical candidate to lay his claims for the office fairly and fully before the council and the public. Too often the death of a legal coroner has been followed by one of his brother solicitors being elected to the office, for no other apparent reason than because he was a solicitor. The claims of medical candidates for the office are so incontestable that only a reasonable interval is required for their admission by the council who have to appoint. This Act is not quite so well known as it ought to be, and we hope all medical coroners will secure a copy of it. There are, we believe, fourteen medical coroners for boroughs, and we hope in due course to hear of at least an equal number of medical deputies being appointed. Possibly also some legal coroners may be as generous as the late Mr. THELWALL. They will have this justification—that an experienced medical practitioner is likely to make a better deputy coroner than a solicitor or barrister who has had no experience whatever.

## Annotations.

"No quid nimis."

### ST. LUKE'S DAY AT THE ROYAL COLLEGE OF PHYSICIANS.

THE Harveian Oration was delivered at the Royal College of Physicians on Tuesday last (Oct. 18th) by Dr. Bridges, before a distinguished auditory, and was generally pronounced to be an admirable and most appropriate address, the text of which we shall publish next week. In the evening the President and Fellows dined in the College, the guests being the Lord Bishop of Rochester, Lord Sandhurst, the Right Hon. Mr. Justice Denman, the Right Hon. H. H. Fowler, President of the Local Government Board; Admiral Sir Edward Inglesfield, K.C.B.; Sir Charles Russell, Q.C., M.P., Attorney-General; Dr. John Peile, Vice-Chancellor of the University of Cambridge; Sir James Paget, Bart., Vice-Chancellor of the University of London; the Rev. G. Salmon, D.D., Provost of Trinity College, Dublin; Mr. T. Bryant, President of the Royal College of Surgeons; Sir Joseph Lister, Bart.; Sir Hugh Owen, K.C.B.; W. E. H. Lecky, Esq.; J. Macvicar Anderson, Esq., President, Royal Institute of British Architects; the Very Rev. Francis Paget, D.D., Dean of Christ Church; Sir Albert Rollit, M.P.; Sir W. H. Flower, K.C.B.; Sir Archibald Geikie, President of the British Association; and Frederic Harrison, Esq. The toast list was very full. The President proposed "The Health of the Queen," and then gave the toast of "The Church," which was responded to by the Bishop of Rochester. Dr. Priestley proposed "Her Majesty's Government," for whom the President of the Local Government Board replied. The "Army, Navy and Reserve Forces"

was given by Dr. Broadbent and responded to by Admiral Inglefield. Dr. Dickinson, Senior Censor, proposed "Her Majesty's Judges," which was acknowledged by Mr. Justice Denman. "The Universities" was proposed by Sir Dyce Duckworth, Treasurer of the College, and acknowledged by the Provost of Trinity College, Dublin. The toast of "Literature and Art" was given by Dr. Russell Reynolds and responded to by Mr. Lecky; that of "Science" by Dr. Pye-Smith, to which Sir A. Geikie replied. "The Health of the Harveian Orator" was proposed by Dr. W. Ogle and responded to by Dr. Bridges. The company did not separate until a late hour.

#### COMBINATION OF MEDICAL MEN TO SECURE PROPER PAYMENT.

COMBINATION seems the order of the day and medical men seem to be catching the infection of it. They have been so long-suffering and patient under a tacit system of non-payment or under-payment by the public that it has come about that while everybody is paid they are left unpaid or are paid last. As we announced in our last issue, the profession in Coatbridge have determined in justice to themselves and all honest people to frame a minimum scale of charges and to issue quarterly a black list of defaulters, or of those who evade the payment of medical debts by the mean system of going from one doctor to another. It is a pity that such means should be necessary. But we are not disposed any longer to blame an honourable profession, confessedly treated very badly. A local paper, commenting on such a state of matters, traces it finally to certain members of the profession who undersell their brethren and demoralise the public. There is some truth in this, and delinquent members of the profession will only have themselves to blame if they are defined and discountenanced. Such a procedure will have no terrors for honourable men in practice, nor for the honest poor, who do what they can to meet the modest charges of their best friend, the faithful medical man, who is at their service by night or day.

#### REMARKABLE RECOVERY FROM CHLOROFORM BY SUSPENSION AND INFLATION.

A VERY remarkable recovery from apparent death from chloroform is related by Dr. Prince in the *New York Medical Record* of Sept. 17th. Chloroform was administered to a gentleman who had a cardiac bruit for the purpose of opening an abscess of the mastoid cells. Just at the beginning of the operation it was found that both respiration and the action of the heart had ceased. The order of these events was not ascertained, but it was thought that the heart was the first to cease. "No time was lost in temporising," but resort was at once had to the inverted position, the patient being suspended by the flexed knees from the shoulders of Dr. Prince, who trotted round the operation-room with his burden so long as his strength lasted. He then stood still and the assistant practised the Silvester method, the body still inverted and suspended from Dr. Prince's shoulders. There was no response. The patient was again placed on the table, to all appearance dead. No time was lost, and the patient was now suspended from the assistant's shoulders and trotted round the room for about one minute. Then Dr. Prince remembered the account of the resuscitation of an infant by blowing directly into the mouth. He stopped, knelt down, put his mouth to the patient's, and drove air from his own lungs into those of the patient. "The chest expanded, the diaphragm, with the weight of the intestines, was raised," and Dr. Prince does not doubt that the flaccid heart was emptied of its blood. After auscultation, in which no sound was heard, artificial expansion of the lungs was resumed, expirations being effected by the elasticity of the chest. This was continued for about three minutes, when

the persevering operators had the gratification of seeing the colour of the lips improve. Another interval for auscultation was allowed, but no sound of natural respiration or pulsation could be detected. Inflation was again resumed and continued for about two minutes, when the gratification was experienced of hearing the first natural effort at respiration. After a short time the operation was finished under ether. Dr. Prince adds: "This is the sixth case of suspended functions which did not respond to either the Marshall Hall or Silvester method, the first five of which recovered under suspension treatment. Without this all would have been lost. The foregoing is the only one that did not respond to the suspension method, and I am under unutterable obligation to Dr. Forest for paving the way to the direct inflation in the inverted position." Both gentlemen are to be congratulated on the result.

#### ERRORS OF DIAGNOSIS.

WE carefully abstained from accepting the accuracy of the Chairman of the Sanitary Committee of the Town Council of Leicester as to the "ignorance and intolerable carelessness" of notification work in Leicester, contenting ourselves with the remark that the charge was one for the medical men to note. We are glad to see that our remark has had the proper effect of stimulating at least one reply in the public papers where the charges appeared. We are alive to the difficulties of diagnosis, and persuaded that errors cannot always be avoided; but there is need for much consideration on the part of the sanitary authority before bringing wholesale charges of ignorance and intolerable carelessness. The following paragraph from a letter signed "Medicus" in the *Leicester Daily Post* suggests that the sanitary authority itself makes great mistakes, which should make it a little kinder in its estimate of human error: "With your permission, sir, and through your columns, I will ask the sanitary committee to answer the following questions:—(1) Whether an infant fifteen months old was sent into the Fever Hospital some three weeks ago—having been certified as suffering from scarlet fever—and was sent out in three days—back home—with an intimation that it was measles from which it was suffering? (2) Whether within fourteen days there was another case of scarlet fever in the same house from which this infant was sent? And (3) Whether, when the sanitary authority observed its error, both children were admitted—the infant readmitted, that is in a state of peeling, together with the other child to whom it had given the disease?"

#### THE QUEEN'S VISIT TO FLORENCE.

A FLORENTINE correspondent writes:—"Queen's Weather" in the 'City of Flowers' is what the residents here are promising themselves from Her Majesty's projected visit to Florence—a visit now placed in the category of 'fixtures' by the presence of the Royal courier in the city, where that emissary has been in treaty with the proprietors of several patrician villas in the suburbs, on one or other of which Her Majesty's choice is expected to fall. Four, or more nearly five, years ago—in the March of 1888—the Queen spent some weeks in the Villa Palmieri, in order, it was said, to combine with her vernal *villeggiatura* a visit to the scenes hallowed byearly associations. Nothing could have been more gratifying, from every point of view, than Her Majesty's sojourn. The Tuscans, and indeed the Italian people generally, were most favourably impressed by the deep and intelligent interest taken in their past and present by the Queen-Empress, and Her Majesty in turn lost no opportunity of signifying, in the most gracious manner possible, her appreciation of all that Florence has to show of natural, artistic and historic attractiveness. Even the weather, which for eight weeks

before the Queen's visit had been broken and inclement, became suddenly so serene and steady as to invite the visits of other royal personages to the city—i. e., the Emperor of Brazil, and King and Queen of Wurtemberg, the Queen of Servia and (in the capacity of hosts) of the King and Queen of Italy—insomuch that a local bard commemorated the 'congestion of royalties' in a distich not yet forgotten by the people:—

'Non si fa passo la gente Fiorentina  
Senza incontrar un Rè o una Regina.'

(We Florentines cannot venture abroad without encountering a King or Queen.) Another feature of Her Majesty's visit scarcely less gratifying to Florence was the increased attention to 'nettezza pubblica' (outward tidiness) on the part of the civic ædiles—a concession to the proprieties seldom vouchsafed to the Florentines or, indeed, to the citizens of any Italian town, but deemed *de rigueur* during the sojourn of a monarch whose subjects have always led the van in public cleanliness and sanitation. The initiative then taken has been more or less of a tradition ever since, and now, in the improved hygienic surveillance practised throughout Italy in terms of the recent 'Codice Sanitario,' above all in the increased attention paid to pure and abundant water-supply, Florence may pose as a 'winter city,' with a right to which she had too long neglected to entitle herself. The exact date of Her Majesty's visit has not yet been communicated to those in authority, but at whatever time it may take place I cannot be wrong in asserting that, of all similar august events, none could be more welcome to Florence or to Italy than the sojourn within the city and kingdom of a monarch so endeared to the Italian nation as the Queen-Empress Victoria."

#### THE LONDON WATER-SUPPLY.

FROM the tables contained in the report of Messrs. Crookes and Odling on the condition of the metropolitan water-supply during August it appears that the water continued to be of excellent quality, the proportions of organic matter present being, as now for some months past, extremely small. In periods of flood or after heavy rainfall these experts occasionally find in the course of their examination a sample which, when viewed in bulk, exhibits a distinct turbidity; and from some cause or other one such instance (a sample of water from the Southwark Company's mains) was met with among the 175 samples examined last month. Dr. Frankland, who examines the water on behalf of the Local Government Board, reports that the water taken chiefly from the Lea by the New River and East London companies was somewhat inferior to that sampled from the same source in July; but the water actually delivered by these companies possessed even a slightly higher degree of organic purity than the samples collected in July. The bacteriological examination of the waters as they left the filters of the various companies by Dr. Koch's process of gelatine plate culture gave the following results:—One cubic centimetre of each water collected on Aug. 25th, 23th and 27th developed the following numbers of colonies of microbes: Kent, 1; Chelsea, New River and East London, 4; Southwark—No. 1 well, 4, No. 3 well, 996; West Middlesex, 6; Grand Junction, 11; and Lambeth, 16. In reference to the high number found in No. 3 well of the Southwark company the engineer of the company wrote to Dr. Frankland as follows:—"In consequence of the construction of the new filters at Hampton it has been necessary to employ a temporary engine and pumps to lift the water from No. 3 filter into the engine wells. In all the other cases, Dr. Frankland's report goes on, the high degree of bacterial purity is very satisfactory, and during the present disturbance it should be spared to maintain this high standard. The condition of the water supplied by the Southwark company has been in question before, and only a few weeks ago we had

occasion to comment upon the results of analysis laid before the Southwark Board of Works by their analyst. Water derived from rivers into which sewage is discharged cannot be expected to approach a high degree of organic purity, but at least we may demand that it should be thoroughly and efficiently filtered before delivery. If the filtering process is suspended even for a short time results of a most serious nature may follow. The Royal Commission on Water Supply resumed their sittings on Wednesday last, when evidence on the supply which might be expected from chalk districts was chiefly given.

#### THE HEALTH OF THE POPE.

AN Italian correspondent writes:—"Whatever rumour may say to the contrary (and more than one ill-omened *canard* is already on the wing), the health of Leo XIII. continues good. True, within the last few days he has had to modify his routine and, for the remainder of the year, will not resume the open-air life he led all the summer in the gardens of the Vatican, where he hardly allowed a day to pass without an excursion to the most charming spot of that charming domain, the Villa of Pius IV., and wound up with a modest refectio in the pavilion of the Torre. All he now allows himself in the matter of out-door exercise is a short turn, weather permitting, in that portion of the gardens in the immediate vicinity of the palace; while as to the giving of audiences, he vouchsafes these only to personages accredited on special business of Church or State. Even to morning mass in his private chapel the privileged outsider is very rarely admitted, and persons of distinction who are reluctant to leave Rome without seeing him can do so only 'sul passaggio'—that is, on his way back from one of the brief turns aforementioned in the gardens. In November next, if his health maintains its present satisfactory tenor, he will resume his ordinary Thursday receptions; meanwhile his daily life for the month of October has been, and is, exactly as I have described it. Since June last he has suspended audiences on anything like a numerous scale; but the time thus gained he devoted with all the greater energy to study and business—to the work, in short, which is at once his discipline and his delight. At present he is engaged in weaving the Encyclical which is to be published on the approaching celebration of his jubilee—an anniversary which is eagerly anticipated by the faithful in all parts of the world, if one may judge from the announcements already made of intended visits to Rome for the occasion."

#### A PLEA FOR THE SIX-YEAR-OLD MOLAR.

THE question whether it is justifiable as a conservative measure to remove teeth in cases where there is overcrowding, with its tendency to destructive caries, and if so, which teeth should be selected and at what age it is most advantageous to do so, was the subject of an interesting discussion at the Manchester meeting of the British Dental Association. The first point was tacitly accepted and the chief argument arose as to the relative advantage of removing the six-year-old molars or the bicuspids. Speaking of the intrinsic value of the molar Dr. Davenport of Paris, who opened the discussion, expressed views which are briefly as follow:—"Lateral contact of the teeth is an essential factor of the normal arch, and good arches cannot be disturbed without injury. After extraction the roots of the remaining teeth move less than their crowns, and so the relations of the grinding surfaces are disturbed and much of the interlocking support of the masticatory surface is lost. When the six-year-old molars are lost a large amount of masticating surface is at once removed and a large space is left which requires much diminution in the size of the arch to obliterate, a proportion as the jaws are unsupported by the remaining teeth so do they approach each other ("shortening

of the bite" as it is commonly called), the lower incisors biting too deeply upon the upper incisors, perhaps flattening inward the lower or pushing out the upper incisors. The bicuspidis are often not well articulated even when fully erupted, and the incisors offer no positive resistance to closure of the jaws, whence it follows that the principal force falls upon the molars. The great importance of the six-year-old molar from a masticatory point of view was acknowledged by all speakers at the meeting, but the question was whether it was in a saveable or an unsaveable condition. If these teeth were badly decayed their removal was indicated; if they were sound, the bicuspidis should be sacrificed. Professor Stack is wont to compare the first molars to veterans and bicuspidis to raw recruits. One member went so far as to say that to extract a sound first molar was almost a criminal offence. On the other hand, some members gave it as their experience that the extraction of the first molars gave much better results than was the case where the bicuspidis had been removed. It was strongly urged by Mr. Rose that if the six-year-old molars were decayed at an early age they should be filled in view of a possible improvement in the general condition of the mouth, and that they should be retained at any rate until the second molar came into position. It was pointed out that the results of symmetrical extraction—that is, of all four teeth—gave much more satisfactory results than was the case if only one or two were so treated. "The best time for the extraction of the six-year-old molars," Mr. Quinby said in his summing up, "is immediately after the twelve-year molars are fully erupted, so as to be in complete occlusion; because this usually, though not always, occurs when the patient is about twelve years of age—that is, before the period of greatest danger to the teeth from decay. There are then plenty of masticators, so the loss of these will not be seriously felt. The articulating surfaces of the twelve-year molars, when they are in occlusion, give a natural support to these teeth, and assistance to prevent tipping and turning in their sockets; and what is of very considerable importance, the jaws have then gained all the growth they are likely to attain for two or three years at least, or until the wisdom teeth have become more developed." This discussion, which of course was simply intended to formulate some general rules, leaving each case to be judged on its own merits, will, it is to be hoped, do something to check the indiscriminate extraction of the six-year-old molar which was so prevalent but a few years ago, and is still too common a practice.

#### NEEDLES IN AN EPILEPTIC.

In the newly issued volume of the Clinical Society's Transactions Dr. Charlton Bastian has recorded a case in which at various times no less than eighty-six needles were removed from different parts of the left side of the body of a female epileptic. The patient was under the care of Mr. James Merryweather, and from him and Dr. Oxley Wilson Dr. Bastian had received the particulars of the case. The patient was a spinster of fifty-five who had been subject to fits from an early age and had on two different occasions been an inmate of an asylum. She is now described as fairly intelligent, with occasional fits of bad temper but no morbid appetites, and her conduct in the workhouse of which she is an inmate is described as good on the whole. The fits are frequent, usually several in a day, but no automatism has ever been observed to follow them. She usually employed herself in sewing, darning or knitting, and before needles were found in her body she often had packets of assorted needles in her possession. The needles have appeared in almost every part of the left side of the body, more especially in the leg. One has been expelled from the mouth during a fit of coughing; so far as is known none have ever passed per rectum. As has been said, eighty-

six in all have been found, and of these no less than thirty-four were removed during a period of two months. The patient does not seem to have been hemi-anæsthetic, and she complained of nothing except a little irritation when a needle was about to emerge. No abscess has even occurred, and no satisfactory explanation is forthcoming as to how the needles got there. As Dr. Bastian remarks, it is surprising that such a number of large needles could have been pushed in and should have made their way through different parts without injuring any vessels or nerves, or apparently causing much inconvenience. In a note appended to the communication reference is made to a case subsequently recorded by Dr. J. D. Craig of a woman, an inmate of an asylum, from whose body 286 needles were taken during life. Three were passed per rectum during sickness and eleven were taken from the tissues after death.

#### EPIDEMIC IN ITALIAN SWITZERLAND.

"RESIDENTS on the Swiss banks of the Lago Maggiore," writes a holiday contributor under date of the 15th inst., "have been much disquieted by the outbreak of an epidemic which, having appeared for the first time some weeks ago among the pupils of an infant school at Brissago, has lately spread to the families of the town and neighbourhood, and now includes the adults of the population. Its chief symptoms are violent emesis and intestinal dejections, accompanied by high fever, which is followed after some hours by remission and finally by complete defervescence. Hitherto no case has proved fatal, but the prostration ensuing on recovery is extreme, and time may yet develop sequelæ of a character more or less grave. At its first outbreak the water and food supplied to Brissago and its environs were suspected, and analysis of these by local experts was made with promptitude and care. The results, however, were in each case negative, and accordingly the sanitary authorities of the Canton Ticino lost no time in despatching commissioners to the seat of the outbreak, if only to minimise the alarm which had taken possession of the population. Their report will shortly be made *publici juris*, and will give the official account of the causation and course of the outbreak and contribute, I hope, to restore confidence to the inhabitants, resident or migratory, of this 'earthly Paradise.'"

#### "ASTASIA-ABASIA."

DR. PHILIP COOMBS KNAPP, of Boston, published a few months ago in the *Journal of Nervous and Mental Disease* a paper with the above heading, in which he gave an account of the various cases, forty-nine in all, which had been published under this name. The text of his paper was furnished by a case of his own, which he fully described as one of "paroxysmal trepidant abasia associated with paralysis agitans." The subject of this combination was an Irishman fifty-eight years of age, who had lived a sober and on the whole healthy life. His troubles began in 1889, when after a catarrh he began to have difficulty in walking and what he called "trembling" in the legs. He also had some pain in the shoulders, especially the left, and some cramps in the legs. His difficulty in walking occurred at the commencement of the act. Then, and when he attempted to turn, he was seized with spasm; his steps became short; there were rapid flexions and extensions of the legs on the thighs, and the thighs on the pelvis; he rose slightly on the toes, while the feet seemed to cling to the floor until the spasm became extreme and the feet appeared for a moment almost to cease to move. A tendency to fall forward was then evident, but he not unfrequently recovered himself and proceeded with a natural gait. His difficulty was increased under excitement, but he had no emotional disturbance. He was directed to practise the "balance step" of military drill with the idea apparently of distracting the attention, and this was

for a time successful in arresting the spasm. He relapsed, however, and when seen some months later the spasm was unchanged in character, but now distinct retropulsion was present and the case bore a very striking resemblance to one of paralysis agitans without shaking. Dr. Knapp evidently regards the case as one of abasia in paralysis agitans. We have frequently protested against the multiplication of names, which are perhaps to a certain extent descriptive, but which bring us no nearer to a true scientific classification. The cases which have been designated by the name "astasia abasia" are for all ordinary purposes cases of so-called functional paraplegia, and we have as yet failed to find any necessity for the introduction of a new name. The old one is perhaps vague and unsatisfactory, but the new one is no better and, we venture to think, unnecessary. As regards Dr. Knapp's case itself, the association of the symptom "abasia" with apparently paralysis agitans is interesting. So far as we can judge, it seems to be an intensification of the disturbance of locomotion which is present in that disease.

#### "A HOME FOR THE DYING."

WE have received from Dr. A. T. Schofield the copy of a circular letter with regard to the above Home. We refer to it the more willingly as we are convinced that there is a manifest need of an asylum which may be resorted to by those sufferers who have passed beyond the hope of effective hospital treatment. Briefly, the history of this movement appears to be as follows: Seven years ago a Scotch lady came to London with the need of this particular class so impressed upon her that she opened, and has maintained with the help of a few private friends, ten beds exclusively for dying people, whom she has tended until the end. So numerous and pressing, however, were the applications for admission to this private home that this lady and her friends felt that the time had come for the establishment of a more permanent refuge for cases of this kind. For this purpose steps have been taken to secure, as a "Home for the Dying," a capacious mansion, together with some two acres of ground, situated in the Upper Avenue-road, St. John's Wood. The institution, named "Friedenheim," will be opened on Nov. 7th next by the Duchess of Teck, accompanied by the Princess May. As we have said, there is much need of a home for cases which are for the most part ineligible for temporary hospital relief. The resources of our medical charities are even now strained to the uttermost, and any addition thereto in the shape of an adjuvant such as that above referred to cannot but be welcome to the benevolent public of London.

#### PRESENTATION TO DR. DICKSON.

THE *Civilian* of Oct. 1st contains the report of a very interesting event—the presentation of a service of plate to Dr. Walter Dickson, on his retirement from the position of medical inspector of the Customs establishment in the London district. The meeting was large, consisting of officers of the out-door department of the Customs. It was held at the Customs House, Thames-street, and presided over by Mr. C. H. Barton, Surveyor-General. The present consisted of a silver coffee pot, teapot, sugar basin and two goblets, which were enclosed in a substantial oak case. Some 540 officers of the out-door department subscribed. The testimony of all the speakers to Dr. Dickson's efficient and kindly service of thirty years and of the esteem in which he was held by the families of the men was very thorough and hearty. This is not the time—may that time be long deferred—to write a notice of Dr. Dickson's character and work, extending over fifty years. Roughly and shortly speaking, his active life divides itself into two main periods—twenty years in the Royal Navy, with manifold

naval experiences in the Baltic, in the Indian mutiny, in China, and thirty years as a medical inspector of the Customs. He has been in many ways a chief promoter of naval medicine and hygiene. Those who know him best will best understand the honours and the regret which mark his retirement from the Customs' service, in which he is succeeded by his son, Dr. T. H. Dickson. Such events are among the pleasantest and the fittest which medical historians have to record. Dr. Dickson's retirement by seniority has been the subject of a very respectful intimation of regret from the Board of Customs through their secretary, Mr. R. J. Prowse.

#### THE PUBLIC HEALTH (LONDON) ACT.

WE gather from the accounts of proceedings under the Public Health (London) Act that sanitary authorities are being encouraged to enforce its provisions to a greater extent than those of the Acts which preceded it. Last week the owners of two houses in Hackney were proceeded against for neglect to carry out an order made by the magistrate, who had himself visited the premises. It is stated that he found them in very bad condition, rooms which were entirely underground were inhabited and used for sleeping purposes, and the waterclosets were faulty. Mr. Rose, before whom the case came on the second hearing, imposed in respect of one house a penalty of five shillings a day from Aug. 12th to Oct. 13th, and a like penalty in the case of the other house, from Sept. 8th to Oct. 6th, the penalties and costs amounting in all to £23 6s. The imposition of these fines will have a salutary influence upon others than the persons immediately concerned. If the owners of insanitary houses learn that neglect to comply with orders for their improvement will be followed by monetary loss which is not merely nominal, the work of sanitary authorities will become much easier, and there will be a general improvement in the condition of tenement property in London. The existence of a large staff of sanitary officials is rendered necessary by the neglect of such persons as the owner of the houses referred to, and this entails a considerable cost upon the ratepayers. The infliction of heavy penalties is the only method of saving the ratepayers expense.

#### PROSECUTION FOR EXPOSURE OF INFECTION.

A CONVICTION, including fine and costs amounting to £2 8s. 6d., was obtained in Worcester last week under Section 126 of the Public Health Act, 1875. The case was one in which a child in the desquamating stage of scarlet fever was allowed to run about in the bar of a public-house. Some conflict of evidence arose as to the precise injunctions of the medical attendant in so far as safety might be ensured by the use of oil for greasing the skin; but whatever the view held as to this, it was clear that no permission was even implied that should have admitted a desquamating child into a public bar. Dr. Mabyn Read gave evidence as to the notification of the disease and as to the child being allowed by its mother to expose itself while in an infectious state. There are few places where risk of infection is greater than in public-houses, and hence we trust the results of this prosecution will serve as a salutary lesson. But another point deserves notice. Hitherto it has been difficult to obtain convictions under the section in question, because the Act requires proof of "wilful" exposure. The Notification Act seems to have stepped in to supply much of the wanting link. Where an infectious disease is notified the parent can rarely plead ignorance as to its nature, and since notification of scarlet fever is almost always, as it was in this case, followed by a visit of the sanitary officials who leave printed advice as to the precautions which it is necessary to take in order to avoid the spread of infection it becomes practically impossible for parents, or other persons in charge, to plead that they

acted in ignorance of the results that might be brought about. Hence, probably, in this case the unsuccessful effort of the parent to shelter herself by the plea that she understood much more than seems to have been sanctioned by the practitioner who had been in attendance upon the child. In the future successful action under the section may largely depend upon the due following up of notification returns by the delivery of printed precautions at infected houses.

#### THE CAPE MEDICAL ACT.

THE dissatisfaction with several provisions of the Act, notably those affecting registered practitioners practising midwifery, has found further expression in a petition to the House of Assembly from about forty medical men practising in Cape Town and the neighbourhood. They find that the clauses in question tend to deter qualified persons from obstetric practice. No greater unkindness and injury can be done to lying-in women. They also complain of the clause preventing the sale of medicines by medical men unless they are also registered as chemists. Another great evil is the wholesale sale, without lot or licence, of patent medicines, made up by irresponsible persons and sold indiscriminately to the public.

#### "PSYCHO-THERAPEUTICS."

WE published in THE LANCET of Aug. 20th, 1892, an article entitled "Psycho-Therapeutics: a Scientific Fragment, by Wm. Dale, M.D. Lond." It has been brought to our notice that a large number of the quotations contained in the paper are the same as those given in the well-known work by Dr. Hack Tuke, entitled "The Influence of the Mind upon the Body." Seeing that Dr. Tuke's name did not once appear in the article, we have directed Dr. Dale's attention to these circumstances and he has forwarded us the following letter of explanation, which, in justice to Dr. Tuke, we reproduce.

Bishopsteignton, Oct. 8th, 1892.

DEAR SIRS,—It is six or seven years, as well as I can remember, since I gathered together the contents of the paper on Psycho-Therapeutics, and I have no record of the places and people from whom they came. Yet I remember we had Dr. Hack Tuke's work in the library of the hospital, where I was physician at the time, and that I made extracts from that work. The article Psycho-therapeutics, let me add, has no pretence to originality; but I sincerely regret that in it I was not able to give as quotations the matter that was not my own, on the ground I have already stated. I have never seen Dr. Tuke's book from that day to this. I hope this explanation will be satisfactory; at least, I have no other to give. I remain, dear Sirs, yours faithfully,

WM. DALE.

P.S.—I think you will see that under the circumstances I was not guilty of any intended plagiarism.

#### REMOVAL OF THE GASSERIAN GANGLION.

ON Saturday, the 15th inst., at King's College Hospital, Mr. Rose operated on a case of inveterate trigeminal tic in a woman aged fifty-six. Inasmuch as both the second and third divisions of the nerve were involved, it was decided after consultation with Dr. Ferrier to attack directly the Gasserian ganglion. This was accordingly done on the same lines as detailed in Mr. Rose's recently published work on the subject ("The Surgery of Trigeminal Neuralgia"). The base of the skull was trephined a little anterior and external to the foramen ovale, and the intervening bridge of bone removed. The dura mater was not damaged by the trephine in this case, but the operation was somewhat protracted on account of severe hæmorrhage from the internal maxillary vein. The third division was traced up into the ganglion and excised and the second division isolated and divided, the ophthalmic trunk being left intact. No attempt was made to remove the whole of the ganglion,

but it was freely divided by the cutting hook as high as possible and broken up with a small curette. The patient has made satisfactory progress since the operation; she is perfectly free from pain and, as far as can be ascertained without disturbing the eye-pad, there is total anæsthesia of the right side of the face, nostril and tongue. The temperature has been practically normal, and the patient expresses herself as very comfortable. There has been a considerable discharge of cerebro-spinal fluid, probably from wound of the dural sheath surrounding the ganglion. This is the seventh patient on whom Mr. Rose has operated. The sixth case proved fatal from septic meningitis, possibly due to contamination through a damaged Eustachian tube. It occurred in a feeble old woman of sixty-eight, who had suffered intensely for many years. In the other five cases there has been no recurrence of the neuralgia, except in one neurotic individual, where the pain, however, has not been severe. The first operation was performed in April, 1890, so that this patient has had immunity from pain for two years and a half.

#### SMALL-POX PREVALENCE.

SMALL-POX still prevails largely at Warrington, some thirty cases a week being notified. The disease smoulders in some of the badly protected Yorkshire towns, as Dewsbury and Halifax, and there has been a distinct appearance in Manchester. The metropolis does not appear to be suffering at all severely, only a few cases being reported per week. All these several facts are, however, not reassuring with regard to the prospects of a general epidemic extension of the disease at a later period. The type of the disease at Warrington appears to be severe and fatal. Already eleven deaths have occurred in the hospital, and hæmorrhagic cases are beginning to occur amongst the 112 who are now isolated there. Small-pox has also appeared in the village of Woodhouse, near Sheffield, and the cases have been sent to the Lodge Moor Hospital.

#### NERVE ENDINGS IN THE INTESTINE AND KIDNEY.

In the *Bulletin of the Johns Hopkins Hospital*, No. 23, a paper is published by Mr. Henry J. Berkley a *résumé* of which appears in a recent number of the *Neurologisches Centralblatt*. His experiments were carried out on dogs and mice, and he found that in the outer layers of the muscularis mucosæ of the small intestine of the mouse a well-developed plexus of fine and coarse fibres exists which in general run parallel to the muscular fibres. Immediately under the muscle in the mucosa are more or less regular bundles of two or three fibres which are arranged around the bloodvessels. Some of these run to the free surface of the gut or of the villi. In the cortex of the kidney generally are numerous nerve fibres. The larger branches run between the tubules, the smaller anastomose in all directions with each other.

#### LIGATURE OF THE VERTEBRAL AND CAROTID ARTERIES IN EPILEPSY.

THE operation of ligaturing the two vertebra arteries, with an interval between the operations, for epilepsy not having given satisfactory results, and having been abandoned both by English and continental surgeons, Dr. Chalot of Toulouse has proposed, and indeed carried out in a few instances, some modifications. First of all he ligatured the vertebral arteries of the two sides at one operation, and subsequently he constricted the common carotid artery, so as to lessen its lumen by about one half, at the same time and with the same incision as he used for the vertebral artery. When this was done an interval of a week or a fortnight was allowed to elapse before the corresponding operation was performed on the other side.

He is not as yet able to speak positively as to the effect on the epilepsy, but there seem to be indications that some improvement has occurred.

#### THE NEW RAG ORDER.

ON account of an increase in the importation of Danish rags and of the continued prevalence of cholera in Northern and Central Europe, which might lead to the shipment of infected rags through Danish ports, the Local Government Board have drawn up another rag order in the usual terms applicable to the circumstances of the case. This takes effect on and after Oct. 26th, and applies to rags, bedding and clothing delivered from Denmark.

#### THE COST OF A SMALL-POX EPIDEMIC.

A CAPITAL object lesson has lately been presented to local authorities who are recalcitrant in carrying out the Acts which provide for the efficient protection by means of vaccination of the populations entrusted to their charge. It has been authoritatively stated that the cost of the recent small-pox epidemic at Brighouse, Rastrick and Clifton in Yorkshire amounted to between seven and eight thousand pounds; and a general district rate of 1s. 4d. in the pound has had to be levied to meet the largest item in this amount—viz., the charges of the hospital administration. Much, if not all, of this could have been avoided if vaccination of infants, followed by revaccination of adults, had been carried out as it should have been. Altogether, 231 cases of small-pox occurred in the district, costing the inhabitants on an average over £30 per case. This figure is in striking antithesis to the few shillings that it costs the ratepayers for public vaccination, both primary and secondary. Perhaps this financial aspect of the question will appeal to those whom a broader public-health standpoint would not affect.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Berlin.*—Professor Hirschberg, the Ophthalmologist, being abroad, is not likely to resume his lectures this session.

*Naples.*—Dr. G. Melle has been recognised as *Privat-docent* in Dermatology and Syphilis.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Antonio Garcia Cabrera, Professor of Anatomy in the University of Granada.—Dr. Isidore Henriette, Professor of the Diseases of Children in the University of Brussels.

THE Società Italiana di Laringologia, Otologia e Rinologia will hold its annual meeting in the Aula Magna of the Roman University on Wednesday, Oct. 26th, at 10 A.M. After the opening address of Professor Vittorio Grazi, the President, a paper will be read by Dr. Alessandro Trifiletti on "The Importance of Laryngology, Rhinology and Otology to the General Practitioner." After business preliminaries, including the constitution of the Sections, the agenda will be proceeded with, and a number of "Relazioni" (reports) assigned at last year's meeting to various experts for the investigation and discussion of debatable or obscure points in laryngology, rhinology and otology will be read and considered.

"PHTHISIS in relation to Life Assurance" will form the basis of a special discussion at the Hunterian Society on the 26th inst., at 8.30 P.M. The subject will be introduced by a paper by Dr. Glover Lyon, and Drs. Pye-Smith, J. E. Pollock, E. Symes Thompson, Sedgwick Saunders and others will take part in the debate.

WE understand that a few appointments to the Indian Nursing Service will very shortly be made by the Secretary of State for India. This service, which was founded on a small scale in 1888, mainly on the lines of the Army Nursing Service, has since been gradually extended to nearly all the larger military stations in India, where it ministers to the needs of the sick British soldier. Candidates must have at least three years' previous training in a general hospital, preference being given to those trained at the larger metropolitan and provincial hospitals, where naturally the widest experience is gained in medical and surgical cases.

THE Royal Commission appointed to inquire into the granting of a Charter for the formation of a Teaching University in London and to modify in any way the Gresham Charter so that it may be best adapted thereto has resumed its sittings. Witnesses on behalf of the Working Men's College, the Birkbeck Institution and the London Society for the Extension of University Teaching have been heard. It would appear that the Commission has completed, at any rate for the present, the examination of the medical witnesses.

THE autumnal general meeting of the Irish Medical Schools' and Graduates' Association will be held at 11, Chandos-street, Cavendish-square, London, W., on Wednesday, Nov. 2nd, 1892, at 6 P.M. On the same evening the Association will dine at the Holborn Restaurant at 7 P.M. Mr. James N. Dick, C.B. (Director-General Medical Department, R.N.), President, will be in the chair.

AT the meeting of the General Council of the Royal British Nurses' Association, to be held at 20, Hanover-square to-day (Friday), at 5 P.M., H.R.H. Princess Christian will preside.

A NEW Italian medical fortnightly has just appeared under the title of *Gazzetta Medica di Pavia*. It is brought out under the auspices of the Pavia Medical Society.

THE death is announced of Dr. Conway Evans, medical officer of health for the Strand district.

## CHOLERA.

#### CURRENT NOTES, COMMENTS AND CRITICISM.

THE report for the week as to the progress of cholera is, on the whole, satisfactory. The statistics for the eighth week of the epidemic at Hamburg, which ended on the 15th inst., were 82 attacked, with 24 deaths, against 173 and 46 respectively during the preceding week, bringing up the total registrations to 17,962 cases, of which 7598 ended fatally. The new cases for the 18th inst. were 11 and 1 death. The patients in hospital had declined to 575. The rapid spread of the disease at Hamburg, once it had really obtained a foothold there, is a noteworthy feature. Up to Aug. 20th the cases seem to have been comparatively few, but by Aug. 27th the attacks had risen to 1000 a day. All the arrangements were dislocated for the moment, and it was only after a period of perplexity and confusion and by strenuous efforts that the local authorities were able to cope with the evil in the way they did.

As regards Holland we learn that there have been 35 fresh cases in the whole country during the past seven days, 9 of which occurred at Utrecht. One case of Asiatic cholera and 1 death from cholera nostras occurred on the 18th at Rotterdam, and 1 fresh case and 2 deaths from Asiatic cholera at Utrecht, while 6 additional cases are reported from various other towns. At Budapest there were 17 cases and 11 deaths recorded on the 18th; at Cracow a few cases;

at Antwerp the authorities have decided to discontinue the daily issue of bulletins, as cholera had disappeared from that city; at Berlin the hospital in Moabit at present contains no case of Asiatic cholera, and as none have appeared for some time past it is intended that the hospital shall shortly revert to its original character as a general infirmary; at St. Petersburg fresh cases continue to appear, notwithstanding the marked decline which has taken place; and as regards Paris and its suburbs, there are some deaths reported from cholera and but few fresh cases. The epidemic at Marseilles, which was of a limited character, appears to be subsiding. There are still numerous cases at Marseilles spread over various parts of the town. This outbreak was attributable, according to Dr. Brouardel, to the contamination of water with sewage. *The Times* correspondent at Brussels informs us that the director of the sanitary service has laid a report before the Superior Council of Health, from which we glean the following information. Between July 21st and October 1st 1135 cases have been reported to the authorities, of which 564 proved fatal. In the port of Antwerp there were 244 cases and 89 deaths. With the exception of Antwerp the places where the visitation has been most marked are those which communicate with the metropolis by water. The provinces of Liège, Limbourg, Luxembourg, and Namur, possessing the purest drinking water, have been very slightly attacked. In view of the slight gravity of the cholera outbreak in Belgium the Government suspended on the 1st inst. the medical control established on the frontiers. The report of the director of the sanitary service shows the futility of these restrictive measures, which are more vexatious than effective. A sounder legislation and the diffusion of a better understanding of the simpler rules of hygiene are, it is stated, surer safeguards against the evil.

We wish, as we have said already, that we were in a position to assure our readers that this decrease and apparently gradual cessation of the epidemic at the present time was a guarantee of immunity in the future; but of that we cannot be at all sure, if we are to follow the lesson taught us by epidemics of cholera in the past. From the accounts that are coming in we are beginning to realise the nature and extent of the scourge which the present epidemic has proved. In Teheran, where the disease began on Aug 4th with a mortality of 14, it rapidly increased, and according to the latest accounts had only recently disappeared. The total mortality amongst the natives is estimated at over 20,000, and out of a very small European colony 21 died. At the outbreak of the malady about 30,000 people fled from the city, but a considerable number died of the disease, which they had already contracted at Teheran. There was, speaking generally, an absence of doctors, nurses, hospitals and all sanitary supervision. At the meeting of the Hygiene Council on the 17th inst. M. Monod submitted statistics showing that the cholera victims in France from April 14th to Oct. 15th numbered 3184. These deaths took place in 212 parishes. In April there were 65, in May 28, in June 107, in July 466, in August 841, in September 1411, and in October 266. In 1884-85 there were 11,685 deaths in 639 parishes. Havre now shows a clean bill of health. It would be very interesting to ascertain the exact results of the bacteriological observations of the cholera that has prevailed so long in and about Paris, more especially of those made during the earlier period of its prevalence. We do not at all desire to decry the systems adopted by other nations and extol our own methods, but we imagine that as far as New York is concerned the unnecessary hardship and evils attending their late wretched experience at that port have been fully recognised and are not likely to be repeated by such an intelligent, clear-headed and practical people as the Americans. We cannot be surprised at the appeals, expostulations and representations that came from the unfortunate passengers arriving by various steamships at New York. It surely cannot be justifiable to adopt a method of detention of ships which compels the healthy to remain in contact with the sick. Apart altogether from all questions of infection, it is obviously cruel to subject innocent and healthy people to the fear of it and under circumstances such as so frequently obtain on shipboard—viz., overcrowding, discomfort of all kinds and probably insufficient or improper food. That strikes us as the best conceivable way of increasing and developing the spread of the disease; whereas a strictly sanitary detention of a ship, the separation and segregation of the sick in hospitals on shore and the dispersion of the remainder, due and proper precautions being of course taken in regard to

them, seems to be the only really practicable course that can be adopted. It is the best and most merciful procedure as regards the sick themselves; it is the only workable one as regards the healthy, and it affords a safeguard as to the future in that it enables the authorities to warn those directly concerned at the localities whither they are going. It has so far worked admirably on the present occasion. Until we have arrived at the end of this epidemic and are looking back at it as a thing of the past it is not becoming to boast, but it may be truthfully said that the arrangements in this country have proved sufficient for the purpose. And, after all, where is there any country that has such direct and constant communication with other countries and with India, the alleged home of cholera, as England? The Red Sea route to India was opened in 1842 and the Suez Canal completed in 1869. Eighty per cent. of the shipping that comes through the Suez Canal is British. Our intercourse with the East is constant, and our commerce extends to every country in the world, and we should consequently be more exposed to the introduction of the disease than any other country. But Great Britain has indisputably not suffered more than her neighbours from epidemic cholera. She has, on the contrary, for very many years past had an almost complete immunity from it. There have been between twenty and thirty instances in which cholera has been introduced into this country, and at the moment of writing it is reported that the medical officer of the port of London, Dr. Collingridge, had removed a case of cholera from the steamship *Biafra* to hospital and detained another steamer, the *Libby*, which had landed a case at Cuxhaven, for fumigation. A vessel had arrived at Belfast Lough from Ibrail, on which a death, believed to have been from cholera, had taken place. It is but right to recognise our indebtedness to the health department for its foresight and administrative capacity and to the port sanitary officers for the vigilant supervision they have exercised and the prompt action they have taken.

By way of conclusion we desire to call attention to the graphic chart prepared for the use of the French Government, representing the daily cholera mortality per million at Paris, Rouen, Havre and Hamburg respectively during the months of August and September and for a portion of the present month. The chart graphically indicates the way in which the disease comported itself and the relation between its rise and fall at these different places. The continuous low-level rate of prevalence of cholera at Paris and its suburbs is in striking contrast to the rapid, almost vertical, rise of the Hamburg outbreak, with its irregular and oblique line indicating its fall. It is also a noteworthy feature in the chart that it shows similar fluctuations of prevalence of the disease at places widely apart, as if in obedience to some common influence.

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### VISIT TO HAVRE.

CHOLERA DIAGRAMS.—THE EARLIEST CASES AT HAVRE.—LATE YET EFFICACIOUS MEASURES.

THOUGH England has so far escaped from the cholera epidemic which prevails extensively in Asia and in Europe, this immunity should not make us unmindful of the very great dangers with which we are still beset. Perhaps it is not fully realised that all the nearest ports, and the ports with which we are in almost daily communication, are, without exception, more or less contaminated with cholera. From Hamburg, on the North Sea, through the Straits of Dover, all down the Channel to Cherbourg there has been cholera in and about every harbour. In some ports the epidemic was severe, in others there were but a few cases; but whether slight or severe, cholera has travelled along the whole coast line. There has been cholera at Rotterdam. I have described the cholera at Antwerp. The epidemic still continues there, and many other small towns in the neighbourhood are infected. Here at Havre I find that ships from Dunkirk are put in quarantine. Near Boulogne, at Portel, 31 deaths from cholera occurred in a few days out of a population of 5327 inhabitants. Some 400 inhabitants of Portel go to Boulogne every day. At Tréport in two or three days 12 persons died from cholera out of a population of 4569, and at Dieppe up to Oct. 4th 40

persons had died from cholera out of a population of 22,700. At Honfleur, whence so much poultry and dairy produce generally is exported to England, there have been cases of cholera, and at Cherbourg cholera so far prevails that the ships arriving here from that port are not allowed free access. Havre, like Antwerp, though itself infected with cholera, imposes quarantine and restrictive measures on ships arriving from other ports where there have been a few cases of cholera. The fact that in some of the ports mentioned there have been barely half a dozen cases does not suffice to remove all anxiety. If the sanitary condition of these ports were thoroughly satisfactory, there would be little cause for alarm. Unfortunately this is not the case; and when once the germs of cholera have been introduced in an insanitary locality it is impossible to say when and with what intensity the epidemic may revive.

At the Ministry of the Interior at Paris I had an opportunity of seeing a map of France. Pins pierced every town and village where cases of cholera had occurred. The result was a perfect forest of pins, stretching from Paris in a north-westerly direction towards the sea and forming thick clusters on both banks of the Seine. It was not till I had examined this map that I realised the widespread nature of the epidemic. It was gratifying to see by the side of this map of France a map of England and Scotland. Twenty-five pins, indicating twenty-five imported cases of cholera, were affixed in thirteen different places. There were six pins in London and the port of London, five at Grimsby, one at Middlesbrough, one at North Shields, one at Tynemouth, one at Blyth, three at Falmouth, four at Liverpool, one at Grangemouth and three at Glasgow. M. Henri Monod, Director of the Poor Relief and Public Hygiene Department at the Ministry of the Interior, explained to me that he had this map prepared to show the members of the French Government and the Consultative Committee of Hygiene for France how England had succeeded in preventing the spread of imported cholera, and to impress on all concerned the necessity of reporting the first cases, for if this were done promptly the danger could at once be stamped out. M. Monod, in his official report to the French Government, speaking of this cholera map of England, says: "Thus in England and Scotland 25 cases of cholera arrived in various ports; 9 patients died, 16 recovered, and not a single inhabitant was contaminated. It is difficult to attribute this result to the climate of England, for in 1832 and 1849, and on several other occasions, the cholera had many victims. We must render all honour to the progress accomplished in public hygiene, and it is certainly not at this moment that England will regret the expense incurred to accomplish sanitary reforms, and to organise in so powerful a manner her sanitary services."

Gratifying as this language must be to all who in England have at heart the cause of sanitary reform it must not blind us to the dangers we still incur. The germs of cholera are scattered along the whole coast line facing England and trading with England, and though great sanitary works have been accomplished in England there still remain dark spots where the cholera could spread as readily as on the Continent.

M. Monod further showed me a very interesting chart, which gives the actual daily number of deaths from cholera occurring in Paris, Rouen, Havre and Hamburg. The lines crossing the chart, which is reproduced on the opposite page, give the absolute number of deaths for each day. The figures to the left show for each day the proportion of deaths per million of the population. Thus we are able to see, simultaneously and at a glance, not only the fluctuations of the four epidemics, but the mathematic demonstration of their proportionate intensity. The difficulty in preparing this chart has been to include the city of Paris, for there the number of deaths, in proportion to the population, is very small. For this purpose it has been necessary to make the proportion per million of the population. I was allowed to have a copy made of this interesting chart, which was courteously placed at the disposal of the Editors of THE LANCET by the Director of the Sanitary Administration of France, M. Henri Monod.

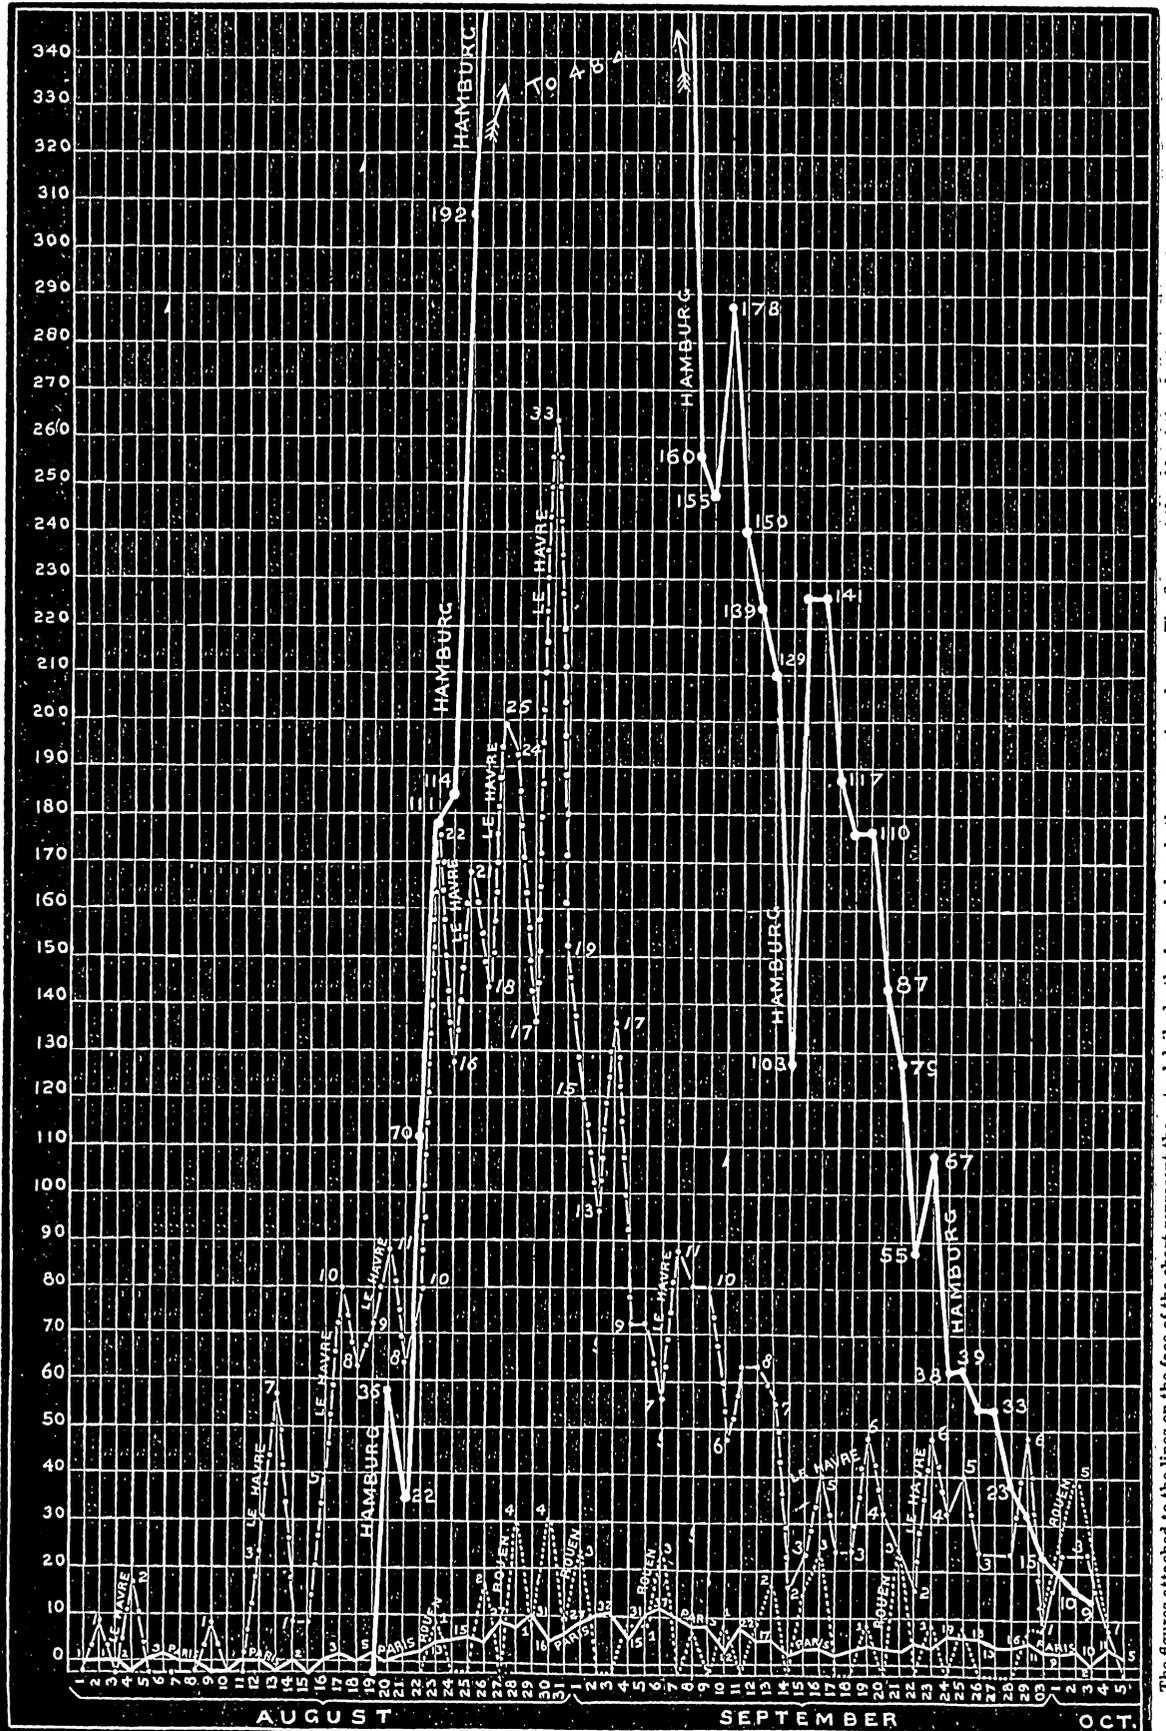

Seeing how high is the proportion of deaths at Havre it seemed most necessary to study on the spot the probable causes of so unfortunate a state. But here as elsewhere there are two causes—the actual cause and the predisposing cause. It seems now clearly established that the infection came by land from Paris and reached Havre before Rouen was attacked. The fatal tendency to deny the existence of cholera is the cause of its epidemic prevalence at Havre.

The first case—not the first death—occurred on July 5th. Dr. Courbet was called to attend a woman sixty-five years old, who lived at the extreme east of the town near the *Barrière d'Or*. This person had been staying at Courbevoie, and had left because there were several cases of cholera in the immediate neighbourhood. Shortly after her return to Havre from Paris, and after having suffered from slight diarrhoea for a few days, she commenced to vomit and felt very feeble. Dr. Courbet found her very anxious, with drawn features, the nose pinched, the extremities cold and the voice much enfeebled. Under treatment the patient soon recovered, but remained very feeble for a considerable time. The house was clean and no other case occurred on the premises. On July 13th another and more marked case was seen in the *Cours de la République*, a broad thoroughfare also to the east but somewhat nearer to the centre of the town. Again, the patient was an elderly woman aged sixty. There was no premonitory diarrhoea. Dr. Courbet, who also attended this patient, states that "in the night violent diarrhoea suddenly set in; incessant vomiting, choleric dejections, terrible cramps, broken voice, anuria, cold extremities, blue colouring of the nails, thready and rapid pulse." The reaction was satisfactorily brought about, but the convalescence was long and painful. There is no reason to believe that this person had travelled. On the next day (July 14th) a workman was taken ill in the *Rue du Château-Graville*. The symptoms were complete, but he also recovered. It was on July 15th that the first death was recorded, the victim being a sailor who lived in the *Rue des Drapiers*. This street is situated behind the *Grand Quai* in a part of the old town which became one of the principal centres of the epidemic. The sailor had been two months at Havre, so he cannot be supposed to have contracted the disease abroad. He died after a few hours' illness, and Dr. Lebreton, who attended him, did not hesitate to consider this as a true case of cholera. The woman with whom this man lodged also died from cholera, but somewhat later. The next death did not take place till July 23rd; the case occurred in the *Rue Viviers*. The third death was that of a rag sorter, and happened on Aug. 3rd. The deaths now became more frequent, yet no official notice was taken of the epidemic. It is important to note the early date of the first cases and the first deaths, then that these cases were scattered in different parts of the town, and there seemed in the earlier stages to be no focus of disease. The first case mentioned was at the extreme east of Havre; at the *Port d'Or*. Early in the epidemic three cases and one death occurred in the *Rue Frère Constant*, at the extreme west of the town. Then there were cases in the centre—in fact, all over Havre; but, on the other hand, when once the epidemic was developed cases occurred in well-defined clusters, proving most conclusively that particular parts of the town were especially susceptible. The reason of such susceptibility I will subsequently attempt to explain.

There are no medical officers of health in France, but there are doctors for epidemics—*médecins des épidémies*—who, on receiving instructions from the Government, have to report and advise upon epidemics. No salary is attached to this post, but travelling expenses may be claimed, as also some compensation for loss of time. The doctor has, however, himself to estimate the value of his time and send in an account, which must be examined and approved by the Prefect of the Police, with the result that an undignified wrangle sometimes occurs between the doctor and the prefect as to the various items. Under such circumstances it is not surprising if some doctors prefer doing the work gratuitously, and it is still less surprising if the work is at times neglected or accomplished in a very hasty and unsatisfactory manner. There is one *médecin des épidémies* for every *arrondissement*. The department of the Seine Inférieure is subdivided into six *arrondissements*, and the *arrondissement* of Havre comprises twelve cantons, involving a distance from one canton to the others of twenty miles and more.

On July 5th, when the first suspicious case was noted, the *médecins des épidémies* should have been informed of it then and there. At Havre the result would have been most beneficial, for this town has the good fortune of possessing as its "doctor for epidemics" one of the most eminent and best-known sanitary reformers of France, Dr. Gibert. For twenty years Dr. Gibert has insisted on the insanitary condition of the town, and it is due to his energetic and eloquent pleading that Havre was the first town in France to institute a *Bureau d'Hygiène*. It will scarcely be credited that more than a month elapsed before Dr. Gibert was informed that there was cholera at Havre. On Aug. 10th he heard from some of his colleagues

CHART REPRESENTING THE PROGRESS AND PROPORTIONATE INTENSITY OF CHOLERA AT PARIS, ROUEN, HAVRE AND HAMBURG DURING THE MONTHS OF AUGUST AND SEPTEMBER AND FOR A PORTION OF OCTOBER. (Vide p. 956.)

The figures attached to the lines on the face of the chart represent the actual daily deaths from cholera in the respective places. The figures at the side of the chart represent the death rate per 1,000,000 of the population in these towns.

what had happened, and at once hastened to the hospital to ascertain what was the true nature of the malady. Convinced by thus seeing the patients of the gravity of the situation, he hastened to send an energetic communication to the Minister of the Interior. It will be remembered that it was on Aug. 14th that the *St. Paul* left Havre with a clean bill of health and brought cholera to the port of Antwerp. The first cases of cholera, it seems now clearly established, occurred at Havre before any cases of cholera were noted either at St. Petersburg or Hamburg. There is also good reason to believe that the cholera was brought from Paris to Havre towards the end of June and the beginning of July. As at that time in Paris every effort was made to deny and to disguise the true nature of the epidemic it is not surprising that it spread broadcast, infecting numerous towns and villages not merely in France, but across the frontier, in Belgium. In spite of these facts and these dates some attempts have been made to infer that the cholera was imported from Hamburg to Havre. Certainly the *Isyria* from Hamburg brought some cases of cholera to Havre, but this ship only arrived on August 23, and, as Dr. Gibert remarked in his paper read before the Academy of Medicine, there had been at that date already seventy-one deaths from cholera at Havre. The proportion of deaths was also such as to denote that the epidemic was of the most virulent character. To those who spoke of choleraform diarrhoea and home cholera, and used other attenuated terms, Dr. Gibert opposed the appalling fact that out of the first fifty cases removed to the hospitals no less than 48 had died. To those who argued that it was not real cholera because the disease did not spread rapidly—and this was a very general argument, especially in Paris—the reply could be given that at the Western Hospital of Havre twelve internal cases had followed upon the reception of cholera patients. Though this showed that the disease could spread a proof was soon forthcoming that with good sanitation the disease did not spread. Orders were given that no more cholera patients were to be received at the Western Hospital; henceforth they were all taken to the Eastern Hospital, which is built on the Tollet system, and consists of isolated pavilions in the shape of the gothic arch, devoid of angles, well ventilated, and surrounded on all sides with light and air. Not a single internal case has occurred in the Tollet hospital, though more than a thousand cases of cholera have been treated there. On the other hand, at the Western Hospital, which is a block building several storeys high, there were but fifty-seven cholera patients and yet this sufficed to produce twelve cases of cholera contracted within the walls of the hospital.

In the town, as in the hospitals, good sanitation has held the epidemic in check. Acquainted with the existence of the epidemic on Aug. 10th only, it was on Aug. 16th that, as "doctor for epidemics," Dr. Gibert was able to propose a plan of defence to M. Louis Brindeau, Mayor of Havre, and M. Lardin de Musset, sub-prefect. This plan was approved. On Aug. 18th the medical practitioners of Havre were gathered together at the Town Hall, the method of procedure explained; and twenty-four doctors then and there placed themselves at the service of the administration, and on Aug. 19th the new system was inaugurated; but what precious time had been lost since July 5th! Dr. Gibert estimates that the methods of disinfection and isolation were not satisfactorily applied before Aug. 26th. On the following day seventy-two cases of cholera were notified. This was the maximum for any one day. On the 30th there were sixty cases notified and thirty-three deaths. This seems to have been the maximum number of deaths recorded in one day. By that time the rigorous measures adopted began to take effect; five days later, Sept. 4th, there were twenty-seven cases, and not half that number of deaths. After Sept. 10th the deaths were below ten per day. During the first eleven days of October there have been only twenty-seven deaths from cholera. But, unfortunately, there are still occasional, though comparatively rare, cases of cholera. The means taken seem to have successfully prevented the disease spreading, but they were taken too late to completely stamp out the epidemic.

M. Louis Brindeau, the Mayor of Havre, whose great energy, courage and activity very materially helped to save the town from worse disasters, carefully explained to me the system adopted. Six police stations were converted into sanitary centres. For day duty eight doctors were attached to these stations; two to the two stations situated in the most popular quarters. It was the duty of these doctors to call at least once in every three hours, and to proceed

immediately to any case signalled in the district. The doctor was accompanied in his visits by a sergeant of police, and on the doctor declaring that the person visited was suffering from cholera the sergeant of police at once telegraphed or telephoned for the ambulance and the disinfecting staff. The presence of the police officer was also very useful and resulted very generally in consent being given for the patient to be removed to the hospital, though the law does not arm the authorities with the power of compulsory removal to the hospital. For this work the doctors were paid 3 fr. a visit, and as the epidemic subsided and there were no visits to be made, the mere fact of calling at the police station will be credited to them as a visit. On the other hand, it was laid down that, however numerous the patients, no doctor was to charge more than 40 fr. for one day's work. At night all the services were centralised at the Town Hall or Hôtel de Ville. Here two doctors had to sleep and two carriages were kept in readiness all night. At present, as cases of cholera are of but rare occurrence, there is but one doctor on night duty. These doctors are allowed 10 fr. per night and 8 fr. for each patient seen—on condition, however, that the total sum does not exceed 50 fr. for any one night. Every case seen by these doctors was entered in a register and communicated to the mayor and the Bureau d'Hygiène. As a result every case was reported, notification to the nearest police station being obligatory on all practitioners, and was at once seen, and removal to the hospital and disinfection of the premises followed with equal promptitude. Arrangements were made that all chemists should supply whatever medicaments were required free of charge to patients, the cost being refunded by the municipality. At one time twenty men and four brigadiers of police were employed day and night disinfecting premises. There are three portable stoves and two larger fixed stoves at the hospitals. Four of these stoves disinfect by steam under pressure, the fifth by heat and steam, which, however, is not under pressure. The disinfection is divided into two distinct operations. The first is the removal of all linen, bedding &c. to the disinfecting stove, excepting such objects as can be burnt then and there. After that the walls, furniture &c. are sprayed over with a solution of sublimate. The second operation is carried out by the architect of the town, who has fifteen men under his orders for this purpose, and consists in the main of scraping the walls, whitewashing them, scrubbing them &c. When once these various operations were strictly applied, the epidemic began to subside. This hard experience has taught, however, many lessons, and throws considerable light on the causes favouring the development of the disease, but I must reserve this phase of the subject for another occasion.

## THE HYDERABAD CHLOROFORM COMMISSION.

WE have received from Hyderabad the following letter which Dr. Wood has addressed to Major Percy Gough, Secretary, Hyderabad, Deccan:—

1025, Chestnut-street, Philadelphia, Aug. 30th, 1892.

DEAR SIR,—I write to acknowledge the receipt of the two volumes of the report of the Hyderabad Commission, and to state that we will present them to the Library of the College of Physicians of Philadelphia, which is the largest medical library in the United States except that belonging to the Government at Washington. Will you please express to His Highness the Nizam the great gratification it has given me that while the Government in England, moved by the clamours of misguided fanatics, has been suppressing scientific researches, in India a ruler should appear who is so wise and so munificent as to do this great thing which His Highness has done for science?

With profound respect, I remain,  
Your obedient servant,  
(Signed) H. C. Wood.

Ed. Lawrie, Surg.-Lieut.-Col., Hyderabad, Sept. 20th, 1892.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 14th inst. the degree of Bachelor of Medicine was conferred on Mr. John Cropper, Trinity.

THE ENTRIES FOR THE SESSION 1892-93.

The entries at the Medical Schools for the ensuing session, so far at least as the metropolitan schools are concerned, are now nearly complete, and by the courtesy of the Deans of the various institutions we have been enabled to tabulate the figures in a manner which will prove useful in many ways. Returns have not been received from either the Scotch or

Irish Schools of Medicine, as work there has been resumed only during this present week. Notwithstanding the fact that the General Medical Council now requires medical students to attend for five years instead of four, the entries at five of the Medical Schools are much larger this year than they were last year. The total number of entries at all the Medical Schools show an increase as compared with last year.

	Analysis of new entries.					Total number of students at present on the roll.				
	General students.	Special students.	Dental students.	Preliminary scientific students.	Totals.	First year.	Second year.	Third year.	Fourth year.	Totals.

<sup>1</sup> Exclusive of those Preliminary Scientific Students who have also entered for the Curriculum or for Special Courses.

<sup>2</sup> Including Bacteriology.

<sup>3</sup> Entry not complete

NOTE.—The Scotch enrolment goes on for nearly a month, yet the statistics cannot be obtained. † Information not supplied.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6153 births and 3382 deaths were registered during the week ending Oct. 15th. The annual rate of mortality in these towns, which had been 16.6 and 17.8 per 1000 in the preceding two weeks, declined again last week to 17.3. In London the rate was 17.1 per 1000, while it averaged 17.5 in the thirty-two provincial towns. The lowest rates in these towns were 8.4 in Croydon, 12.0 in Derby, 13.0 in Bolton, and 13.4 in Cardiff; the highest rates were 20.2 in Liverpool, 20.9 in Blackburn, 23.3 in Salford, and 30.6 in Preston. The 3382 deaths included 389 which were referred to the principal zymotic diseases, against numbers declining from 989 to 505 in the preceding six weeks; of these, 123 resulted from diarrhoea, 77 from measles, 59 from diphtheria, 53 from scarlet fever, 39 from "fever" (principally enteric), 34 from whooping-cough, and 4 from small-pox. No fatal case of any of these diseases occurred last week in Derby; in the other towns they caused the lowest death-rates in Plymouth, Wolverhampton, and Halifax; and the highest rates in Manchester, West Ham, Oldham, Salford, and Preston. The greatest mortality from measles occurred in West Ham, Brighton, Bradford, Huddersfield, Oldham, and Salford; from scarlet fever in West Ham; from whooping-cough in Nottingham, Birkenhead, and Preston; from "fever" in Sunderland; and from diarrhoea in Leeds, Manchester, Gateshead, and Preston. The 59 deaths from diphtheria included 46 in London, 2 in West Ham, and 2 in Manchester. One death from small-pox was registered in Liverpool, one in Manchester, one in Oldham, and one in Leeds, but not one in London or in any other of the thirty-three large towns; four cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 7 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3796, against numbers increasing from 3052 to 3628 on the

preceding eight Saturdays; 503 new cases were admitted during the week, against 369 and 412 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 184 in the preceding six weeks, further rose to 241 last week, but were 32 below the average. The causes of 70, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Bradford, Leeds, Sunderland, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17.1 and 18.5 per 1000 in the preceding two weeks, declined again to 18.0 during the week ending Oct. 15th, but exceeded by 0.7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12.6 in Leith and 13.4 in Dundee to 20.6 in Perth and 21.5 in Greenock. The 500 deaths in these towns included 33 which were referred to measles, 16 to scarlet fever, 13 to diarrhoea, 8 to whooping-cough, 3 to "fever," 2 to diphtheria, and not one to small-pox. In all, 75 deaths resulted from these principal zymotic diseases, against 84 and 78 in the preceding two weeks. These 75 deaths were equal to an annual rate of 2.7 per 1000, which was 0.7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 12 to 22 in the preceding three weeks, further rose to 33 last week, of which 17 occurred in Edinburgh, 8 in Glasgow, and 4 in Leith. The deaths referred to scarlet fever, which had been 17 and 16 in the previous two weeks, were again 16 last week, and included 11 in Glasgow and 2 in Edinburgh. The 13 fatal cases of diarrhoea showed a further marked decline from recent weekly numbers, and included 8 in Glasgow. The 8 deaths from whooping-cough corresponded with the number in the preceding week, and included 6 in Glasgow. The fatal cases

of diphtheria, which had been 10 and 6 in the previous two weeks, further fell to 2 last week, of which one occurred in Greenock and one in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had risen from 66 to 84 in the preceding three weeks, were 82 last week, and were 29 below the number in the corresponding week of last year. The causes of 59, or nearly 12 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21.5 and 20.0 per 1000 in the preceding two weeks, rose again to 20.7 during the week ending Oct. 15th. During the thirteen weeks of last quarter the death-rate in the city averaged 23.1 per 1000, against 17.1 in London and 16.1 in Edinburgh. The 139 deaths in Dublin during the week under notice showed an increase of 5 upon the number in the preceding week, and included 4 which were referred to different forms of "fever," 3 to diarrhoea, and not one either to small-pox, measles, scarlet fever, diphtheria, or whooping-cough. In all, 7 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.0 per 1000, the zymotic death-rate during the same period being 1.7 in London and 4.7 in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 3 in the preceding two weeks, further increased to 4 last week. The fatal cases of diarrhoea, which had been 20 and 9 in the previous two weeks, further declined to 3 last week. The 139 deaths registered in Dublin last week included 34 of infants under one year of age and 31 of persons aged upwards of sixty years; the deaths of infants showed a slight further increase upon those recorded in recent weeks, while those of elderly persons showed a further decline. Five inquest cases and 5 deaths from violence were registered; and 46, or nearly one-third, of the deaths occurred in public institutions. The causes of 9, or more than 6 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

#### MOVEMENTS OF MEDICAL STAFF.

Surgeon-Major Foss (lately on retired pay) has been posted to Dublin for duty. Surgeon-Captain Bond has embarked for duty in Barbadoes. Surgeon-Major-General Madden has resumed his duties as Principal Medical Officer at Malta. Surgeon-Captain Burnside has been transferred to the North British district. The following officers from the School of Instruction at Aldershot have joined the stations named:—Surgeon-Lieutenants Thurston and Smythe, London; Surgeon-Lieutenants O'Reilly, Walker, Moore, Jones, Marden, McDermott, Hodgens, McNaught, and Conden, Ireland; Surgeon-Lieutenants Faichnie and Mansfield, Colchester; Surgeon-Lieutenants Lewis and Chambers, Dover; Surgeon-Lieutenant Slayter, York; Surgeon-Lieutenant Reed, Devonport; Surgeon-Lieutenant Erskine, Woolwich; Surgeon-Lieutenant Thompson, Chatham. Surgeon-Major McNece has been granted sick leave to England from Bombay.

#### ARMY MEDICAL STAFF.

Surgeon-Captain J. D. Moir has resigned his appointment as a medical officer attached to the 2nd Battalion Grenadier Guards. The following officers have been ordered home during the trooping season on completion of tour of Indian service:—Oct. 8th, Surgeon-Major W. L. Lane, M.B., and Surgeon-Captain S. C. Phipson; Dec. 31st, Surgeon-Captain F. A. B. Daly, M.B.; Jan. 11th, Surgeon-Captain T. H. Corkery; March 12th, Surgeon-Major G. D. Bourke and Surgeon-Captain H. H. Brown, M.B.; March 25th, Surgeon-Captain F. T. Skerritt; April 6th, Surgeon-Lieutenant-Colonel N. B. Major and Surgeon-Captain F. S. Le Quesne, N.C.

#### YEOMANRY CAVALRY.

Herts: Veterinary-Lieutenant W. S. Harrison resigns his commission.

#### INDIAN MEDICAL SERVICE.

Surgeon-Major W. K. Hatch, I.M.S., proceeded to England on privilege leave on the 24th ult. per s.s. *Oriental*. Surgeon-Captain C. J. Addison, A.M.S., is expected from England for duty in India. Surgeon-Captain C. M. Moore, I.M.S., proceeded to Agar from Deesa on the 23rd ult. to join the 2nd Regiment Central Indian Horse. Brigade-Surgeon-Lieutenant-Colonel G. Thomson, I.M.S., has been appointed Principal Medical Officer of the Peshawur district. Surgeon-Captain J. E. Trask will proceed to Bombay to take Medical Charge of the 3rd Dragoon Guards during their voyage to Natal in the R.I.M.S. *Clivo*. Surgeon-Captain G. S. Thomson, M.D., has been appointed to the Medical Charge of the 4th Regiment (1st Battalion Rifle Regiment). Surgeon-Captain H. C. L. Arnim has been appointed to the Medical Charge of the 10th Bombay Infantry. Surgeon-Captain G. E. Fooks arrived at Bombay on the 2nd ultimo from furlough in England. Surgeon-Captain J. Fyrrer, M.B., M.S., has been appointed to the Civil Medical Charge of the Muttra district, in addition to his military duties, from the forenoon of Sept. 1st, 1892. Surgeon-Major J. J. Falvey, A.M.S., having been struck off the strength of the Bengal command, is directed to return to England on transfer to the home establishment. Surgeon-Captain H. W. Stevenson and Mr. H. A. Hall respectively delivered over and received charge of the Yerrowda Central Gaol on Aug. 31st, 1892. Surgeon-Major H. McAlman, M.D., and Assistant Surgeon P. P. Moolan respectively delivered over and received charge of the Ratnagiri Gaol on Sept. 22nd, 1892. Surgeon-Captain J. P. Barry, M.B., and Surgeon-Major J. S. Wilkins, D.S.O., respectively delivered over and received charge of the Bijapoor Gaol on Sept. 22nd, 1892. Surgeon-Major W. Barren and Surgeon-Captain R. W. S. Lyons, M.D., respectively delivered over and received medical charge of the Yerrowda Central Gaol on Sept. 26th, 1892.

#### NAVAL MEDICAL SERVICE.

The following appointments have been made:—Staff Surgeon William Rogerson White, B.A., M.B., has been promoted to the rank of Fleet Surgeon. Surgeon D'Arcy Harvey to the *Vernon*, additional, for disposal; and Surgeon C. Alsop to the *Melita*. Surgeons and Agents: W. O'Donnell at Tribane; J. E. Lanyan at Portnoo.

#### THE LATE DEPUTY-SURGEON-GENERAL FASSON.

The Edinburgh Royal Infirmary has sustained a great loss by the death of its superintendent on Saturday, the 15th inst. The late Deputy-Surgeon-General Charles Fasson united in his personality several qualities which are not invariably found associated together. He possessed qualities of head and character. As a young man he was very handsome, with a pleasant, genial expression of face and a fine manly presence. He was a very able organiser and administrator and was universally recognised as an admirable official at the head of a big institution like the Edinburgh Royal Infirmary. His judgment was sound; he was full of initiative, and at the same time industrious and conscientious, added to which he was such an amiable and courteous gentleman, with the stamp of sincerity and truth in his bearing and intercourse with everybody, that he was not long in making friends in Edinburgh, where he was greatly respected and beloved. When he relinquished the Army to take up the post of Superintendent of the Royal Infirmary he went to Edinburgh as a comparatively unknown man and a stranger there, and it is pleasant to know that his regard and affection for its people went on increasing year by year and he delighted to recognise and express this to his friends. Deputy-Surgeon-General Fasson's service in the army extended throughout a period of about twenty-seven years. He had seen a good deal of active service abroad, notably in the Indian Mutiny. At the time of his retirement he held the post of Registrar at the Herbert Hospital, Woolwich. His military service and training, no doubt, proved advantageous to him subsequently in civil life, at the head of a large hospital. He was appointed to the Edinburgh Infirmary in 1871. When the present buildings were opened the duty of transference from the old infirmary fell to him, and he carried out the work with great ability and to the entire satisfaction of the managers of that institution. He held the post of superintendent from 1871 to the time of his death, and the good feeling that existed between the medical staff, the managers and himself was thoroughly mutual. He had the sincerest interest in the welfare and progress of the Edinburgh Infirmary and University. Deputy-Surgeon-General Fasson's health had lately been delicate. He had an apoplectic seizure not long ago, which was followed by hemiplegia; he was in his seventy-second year at the time of his death. His brother was a distinguished army medical officer, and died in the service some years ago.

#### SOLDIERS' RATIONS.

We recently called attention to the advisability of doing something in the way of providing the soldier with the means

of procuring some refreshment before his early morning parade, such as a cup of tea or coffee with a little bread. A cup of cocoa would really be preferable to either of the other beverages, especially during the cold weather, but this might fairly be left to the soldier's individual choice. We notice that this question of the soldier's ration forms the subject of correspondence in some of the Indian journals. The soldier in India is exempted from payment for groceries whilst in the field; the Indian Government issues these free on active service. But some of our soldiers in India are asking for the charge for groceries to be abolished altogether, and contend that when they went to India they understood that rations were issued free to the British soldier whilst serving there. Complaints are also made as to the bad quality of the rations supplied. On the other hand, and with much greater regard to accuracy, we think, others contend that it is entirely the soldier's own fault if he is not supplied with good rations, and that it is the cooking that is to blame. A soldier in India has only to complain of his rations and his objection, if reasonable, is always attended to at once. The natives of India are usually excellent cooks; still it is not every native that can cook, and it is not always easy to secure good ones; moreover, the cook-houses are not always so clean or so good as they might be. These are matters, however, which, after all, greatly depend upon the internal economy of a regiment. The cooking for the soldier in India is really an important consideration as far as the maintenance of his health and strength is concerned, and no reasonable pains should be spared to make the soldier contented in this respect.

#### THE FALL IN THE RUPEE.

The curtailment of income of officers and others serving in India by the great fall in the value of the rupee is really a serious matter. Medical officers of course come in for their share in this unfortunate loss with the rest of the army, and civil officials, and those who have to transmit money home—as so many have—for the support of their wives and families and the education of their children are great sufferers. There is no doubt that the Indian Government is fully alive to the discontent which exists and is spreading amongst the members of the European services in India, and some intimation as to the action that will have to be taken, sooner or later, by the Secretary of State and Treasury in this country is anxiously looked for.

#### PROGRESS OF CHOLERA IN INDIA.

According to the latest intelligence in the Indian papers it would appear that cholera is not only prevalent in the Bittan country, north of Gomal Pass, but has also broken out in the Wano Post in Waziristan, lately occupied by the Afghan troops. Cholera is also stated to be rapidly spreading in Peshawur, both in the city and cantonments. The Royal Welsh Fusiliers are under canvas, and there are cases also in the Royal Artillery and Royal Scots Fusiliers. In cantonments the epidemic appears to be confining itself to Europeans only. Brigade-Surgeon-Lieutenant-Colonel Thomson has arrived from Patiala and taken over the administrative medical charge from Brigade-Surgeon-Lieutenant-Colonel Brown.

#### THE LATE DEPUTY-INSPECTOR-GENERAL BRAKE, R.N.

One of the old school of naval medical officers, Mr. Wm. Newman Brake, R.N., Deputy-Inspector-General of Hospitals and Fleets, passed away at Porchester, Hants, on the 5th inst., aged seventy. He was an old St. Bartholomew's man and was a dresser to Lawrence. In his early career in the service he was an esteemed friend of the late Captain Burgoyne, who went down in H.M.S. *Captain*. In later years he had the confidence of the two present naval lords, Sir Anthony Hoskins and Sir Frederick Richards. The deceased officer entered the navy in April, 1845, was promoted Staff-Surgeon in January, 1855, Fleet-Surgeon in 1867, and retired with the rank of Deputy-Inspector-General in September, 1878.

#### CANTONMENT GENERAL HOSPITALS.

Funds have been allotted for the completion during the current year of general hospitals at Bareilly, Allahabad, Jubbulpore and Peshawur.

#### THE LATE SURGEON-MAJOR CARLAW, M.D.

Surgeon-Major J. Carlaw, M.D., Retired List, Army Medical Department, died at the Crescent, Sandgate, on the 10th inst. He joined the army April 22nd, 1858, became Surgeon-Major April 1st, 1875, and retired Aug. 12th, 1878.

The "Diario Oficial" of the Republic of Paraguay

announces that Dr. William Stewart, British subject and Honorary Colonel of the National Army, is now a Paraguayan-citizen.

### MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—I am particularly anxious to make it plain that, although these coöperative medical businesses grotesquely masquerading as provident institutions must be dealt with by appearing to treat harshly the surgeons connected with them, this is more apparent than real. It is equally for their benefit as for the benefit of their professional brethren that this course is pursued. I may be permitted to point out that, as a matter of fact, it was at the direct request of several surgeons to medical aid associations that the Medical Defence-Union has asked the General Medical Council to express its judicial opinion that their conduct is "infamous in a professional respect" within the meaning of Section 29 of the Medical Act, 1858. These surgeons recognise that only by this means can a radical reform be accomplished. May I ask medical aid surgeons who have not yet communicated with me to do so? I will take care that their names shall in no way be made public without their express permission, for I know this might lead to their instant dismissal; but their coöperation will be valuable. May I also appeal to the practitioners who know the workings of these aids to enlighten their brethren? Many men resident in large towns do not understand the question, while those in small towns have too good reason to appreciate the evil consequences of the system. The following resolution would be a fitting one on which to raise the question for discussion at meetings of the branches of the British Medical Association and other medical societies: "That anything which tends to degrade the professional standing of medical practitioners, to diminish their self-respect or to detract from the quality of their professional work is detrimental to the public interest, and that the system and practice carried on by medical aid associations is calculated to produce this evil result."

I shall be glad to forward to any medical man a copy of my letter to the General Medical Council or a sheet of a petition addressed to that Council praying that this question may be taken into their consideration. The scope of the word "covering" is far too wide to allow of its arbitrary restriction to those cases where the unqualified person "covered" actually and personally practises medicine. In its intention and without unduly stretching language it includes by implication those cases in which, although not personally engaged in the actual practice of medicine, an unlicensed person is pecuniarily interested in the conduct of such practice.

The unqualified man who toils not but participates in fees earned by a duly qualified medical man is in a sense a much greater offender than the unqualified man who actually works and earns money, although to do this he occasionally is "covered" by a qualified man. The offence of the coverer in the former case, in thus putting his licence at the disposal of unqualified persons, is surely not less professionally discreditable? But, even apart from the "covering" line of argument, I contend, with regard to the authority of the General Medical Council in this matter, there is no *non possumus*. If the self-evident proposition be accepted that anything which tends to degrade the professional standing of medical practitioners, to diminish their self-respect, or to detract from the quality of their professional work is detrimental to the public interest, and if it be demonstrated that the system of medical aid associations does these things, it follows that not only is the profession being deeply injured, but, what is of more importance, the public suffer also. Under such conditions the General Medical Council can hardly come to any other conclusion than that the toleration and sanction of this system by duly qualified practitioners are professionally "infamous," and the Court of Appeal has held that if the Council, acting *bonâ fide* and after due inquiry, adjudged a medical practitioner guilty of "infamous conduct in a pro-

essional respect," no court, not even the House of Lords, has jurisdiction to review their decision.

The evil of these medical aid associations is at last being recognised by the lay press of the country, which with almost one voice is now crying out against the abuse in far stronger language than in even the medical journals. When Mr. Masterman told the General Medical Council that since the foundation of this new-fangled medical system a frightful rise in infant mortality was taking place in Stourport, its significance was disputed and not recognised, as I will show it should have been. Mr. Masterman says: "For the ten years ending 1889 the average death-rate was 15.0—1890, 19.2, 1891, 20.23—for the month of January, 1892, 37.7 per 1000, and in the rural districts still higher—in other words, forty more persons died in Stourport, or, with the district, sixty above the average." In reply it was said that this increase of the death-rate did not apply particularly to members of the Medical Aid Association, but to the population as a whole. It was not shown, however, that these two things—(1) the Medical Aid Association and (2) the population as a whole—are practically identical. In 1891 the population of Stourport was 3504, while the number of members receiving medical attendance from the Medical Aid Association was 3058, although it is probable that some small proportion of these lived outside the town.

All thoughtful men must recognise how directly the public suffer by this system; while with regard to ourselves I have no hesitation in saying that no greater injury, no greater insult, no greater systematic robbery, has ever been offered to, or submitted to by, the profession.

I am, Sirs, your obedient servant,

LESLIE PHILLIPS,

Secretary, Medical Defence Union (Limited).

Birmingham, Oct. 18th, 1892.

To the Editors of THE LANCET.

SIRS,—I see in a leading article which appeared in THE LANCET of last Saturday you challenge us, the medical officers of these societies, to defend our position, and I beg formally to accept the challenge. I am of course aware that in opposing the opinion of the editors of a journal by letters addressed to themselves I am going to law with an absolute sovereign in the courts of his dominions, and that, even when I am obliged to comment unfavourably on your remarks, I have to rely solely on your sense of justice to give my reply publicity. Some three months ago a correspondence on this subject appeared in THE LANCET, and then our supporters gained so complete a victory that our last two letters remained, and still remain, unanswered. We should therefore, it seems to me, be justified in replying to a renewed attack by asking our opponents, if their courage has revived, to reply to these letters, and I assert, without fear of contradiction, that when you—in spite of the fact that when last assailed we repelled the attack and silenced the guns of our enemy—pronounce our position "indefensible" you do us a great wrong. Our position as that of men without capital can be justly compared only with that of men who have not practices of their own, and I therefore, in commenting on your remarks, shall have frequently to contrast it with that of assistants to private practitioners. I wish, then, to premise that want of capital is the point on which we agree, and that I do not say we are in the position of assistants to the associations.

I shall now proceed to criticise such of the statements in your article as seem to require it. You assert that medical associations are "by no means creditable to the working classes," but as you give no proof of the statement, and as we hold an exactly contrary opinion, we can only say we are amazed to find anyone differ from us. Doubtless you have reasons for your opinions. May we ask you to let us know them? You tell us we receive "a scanty allowance," and our answer is that it is more than we could get in private practice or we should not accept it. How can you taunt us with being badly paid when you publish advertisements every week wherein qualified men of mature years, with good testimonials and many other advantages, are offered salaries of £70, and even £50, per annum in-doors? Very rarely indeed do you advertise more liberal offers to men without capital than those of medical aid societies. A few of your words describe so exactly the position of an assistant to a firm of medical men that I may be allowed to quote them in full:—"The medical officer is made not only to do medical duty, but to make money for those whom he serves. In other words, the Medical Aid

Association is a 'business,' the work of which has to be done and can only be done by the medical officer, but the profits go to the association, *alias* the company." How many thousands of pounds are yearly earned by the toil of unfortunate medical assistants at work which the principals cannot do (they are doing already as much as they are capable of, suppose)? Where does this money go if not into the pockets of "the firm"? Can you expect an assistant to care where it goes unless you offer him a share of it? Would it not be better for him to pay to an association 5s. out of each midwifery fee he earns than to pay them all to an employer in private practice, as many assistants are obliged to do? The answers to these questions must, we believe, tend to show that the *employé* of the association is in a better position than that of an ordinary assistant.

You say that "there is much to be said" for the view that the medical officers "cover" the associations because the latter are "profitably interested in medical practice." We shall be glad to hear any part whatever of the "much," and meanwhile express our opinion that the contention is childish, and proceed to give our reasons for thinking so. Taking the words as they are used, without any qualification, we see the absurdity the moment we reflect that our wives and children, our servants even, and the tradesmen we employ, are "profitably interested" in our practices. Our opponents now probably will wish to qualify their expression and will tell us they meant a "direct monetary interest." Let us agree to this and consider the new view they put before us. Cases occur daily in which, a medical man having died, an assistant or locum tenens carries on the practice till it is sold, or a relative of the deceased qualifies, or his widow marries another medical man, or in some instances indefinitely. Is the assistant to be considered guilty of "covering" in such a case? Similar cases are those in which a practitioner's widow sells a practice for an annuity to be paid out of, or for a percentage of, the proceeds. Similar also are the cases where a lay friend advances money to buy a practice on the understanding that he is to be repaid out of the proceeds. In none of these cases could we justly punish the medical man, and yet if we are not prepared to do so we must abandon altogether the phrase "profitably interested."

You blame us for taking well-to-do patients from other medical men; but all other practitioners do the same. Is there a case on record of a medical man refusing to treat the ex-patient of a professional brother whose fees are higher on the ground that the patient was rich and could afford to pay the higher fees? 'Till you produce such instances you cannot justly accuse us of doing worse than others. You pass an unfavourable judgment on certain employers who refused to raise an *employé's* salary after five years' service, but you cannot expect us to agree with you till you show us that the *employé* was worth more than he received. Is his market value, as tested by your advertisement columns, greater than his present income? If so, why does he not get that larger salary elsewhere? Can you assure us that the association in question did not intend their refusal as a gentle intimation that a resignation would be accepted, or that they were not restrained from dismissing him solely by the thought that they would thereby throw him on the tender mercies of his fellows, who seldom give more than £150 a year? Since you have passed sentence on the employers, we presume you have the information required to enable us to judge correctly, and we respectfully ask you to make it public.

You assert that the income of medical associations is "derived solely from medical fees," and here, again, we cannot agree with you. The members know that only a part of their subscriptions goes to pay their medical officer, for out of them have to come the rent of the consulting-rooms and surgery, the cost of drugs, of conveyance, of fire and light, of instruments, and of many other items. If after all these are paid a portion of the fund is left it must belong to the association, for the medical man has had what his agreement entitled him to. If the association feels itself strong it returns a part of his subscription to each member, as it has been proved by the existence of a surplus that they have paid too much. If it fears that "bad times" may come it provides for them by buying out the consulting-rooms &c., or by investing the money so as to secure an income for a bad year; so that the medical officer's salary, the rent and so forth may be forthcoming even should some calamity reduce the members to half their previous numbers. It would seem from your article that you think it reasonable that associations should rent houses, but infamous that they

should buy them. Is my view of your meaning correct? We, Sirs, have escaped from the slavery, the hard work and the bad pay which were ours as assistants to medical men to comparative freedom, comparative ease and comparative affluence. The working classes were oppressed by our oppressors, for if they sought cheap dispensaries they were given cheap and even worthless drugs; and if they joined clubs they were no better off in this respect, and were bullied into the bargain. We united our forces; their pence provide us with a competency; they buy us drugs and supply us with all other essentials; and we laugh at our former masters. Of course the latter are not satisfied. Not only have their slaves escaped them, but they have taken off what the masters regard as their private property, their *matériel*, and both reduce their income directly, and by reducing competition raise the salaries of assistants. That line of action which causes them loss they naturally consider low and disgraceful, and they will do their utmost to put down the associations and to force us to serve them as of old. A great victory has been theirs of late, for they have won over—we say it with deep emotion—the Editors of THE LANCET to their way of thinking. We feel it much. You threw open your columns to us last summer, and metaphorically saw fair play while we conquered. Our opponents either remained silent voluntarily or, becoming unparliamentary under the sting of defeat, were refused publication. Now you seem to have forgotten all this, and publish the astonishing announcement that we hold an indefensible position!

A step further is to be taken, you say, and the subject brought again before the General Medical Council. Well, what reason have we for thinking that this body is less wise now than it was last May, when it decided that it was "not their business"? Does anyone fancy these gentlemen are foolish enough to enter on a hopeless contest with the democracy of this country? As well might a porcelain vase expect to collide victoriously with an iron cauldron as the General Medical Council to reduce to their former, or even keep in their present, position those "mechanics and tradesmen" whom you seem to value so little. When Mrs. Partington's mop avails against the tide then will the Medical Defence Union subdue the people, but till then the members of the Union would find throwing stones at the moon a more remunerative occupation than attacking such deservedly popular institutions as the Medical Aid Associations.

I must apologise for the length of this letter, which is due to the length of your article against us.

I am, Sirs, yours sincerely,

Oct. 18th, 1892.

VERAX.

To the Editors of THE LANCET.

SIRS,—Dr. Leslie Phillips, in his paper about Medical Aid Associations, takes an entirely one-sided view as to the small fee the doctor receives for his work. As a matter of fact the drudgery of a club practice, at least in the provinces, is not done by the doctor himself, but by his unfortunate assistant, who in nine cases out of ten is unqualified. By your kindness I have before now expressed my views against the hateful practice of putting unqualified men in charge of surgeries; but I am not going to ignore the proper unqualified man, if I may be allowed to so call him—I mean one who has passed all but his final, but for some reason cannot qualify. I contend that qualified men cannot and will not do the same amount of drudgery work as the unqualified. The major portion of a club and dispensary practice does not require a qualified man, as it consists in treating nothing particular, but almost entirely a class of chronic hypochondriacal females who really visit the surgery for a gossip with the doctor, and in ninety-nine cases out of a hundred a bottle of Epsom salts and burnt sugar will cure all of them. I can assure you, Sirs, in a practice like the above an M.B. Lond. or F.R.C.S. Eng. would simply be lost. He would have no opportunity of utilising his superior knowledge. My predecessor was an unqualified man, but with no medical education whatever. He had not even passed a preliminary examination and had never been inside any hospital or infirmary attached to any university; in fact, he professed to be quite ignorant of the names of any of the bones of the body, and even of any of the diseases he treated. Yet for a period of nearly ten years he had charge of a surgery, attended midwifery, performed vaccinations, visited the people's homes and prescribed at the surgery. I confess I cannot do the same amount of work as this person, nor am I ashamed to say that I cannot diagnose the cases so quickly as he did, nor talk so

professionally as did my predecessor to the patients. Without a doctor the Medical Aid Association could not exist, and if Dr. Leslie Phillips could infuse into doctors a feeling of unanimity to refuse to accept the medical officership of these Medical Aid Associations, then some good would result. But in these days of competition and the multiplying of quack remedies what one doctor would refuse fifty are ready to accept. My principal has actually a dispensary charging the modest sum of a halfpenny a week for children up to the age of fourteen and one penny for adults. These sums include visits and medicine and appliances in case of accidents. Out of these deduct commission for collector, price of labels, corks and physic, then see what is left for the doctor. By these clubs and dispensaries I assert more work is put on the doctor for but a small fee, and the people are able to spend more in drink. This is the case in the town I am in now, and I am sure there are many who could corroborate me. Thanking you in anticipation,

I am, Sirs, yours faithfully,

Oct. 17th, 1892.

GENERAL PRACTITIONER.

To the Editors of THE LANCET.

SIRS,—I have read with much interest your article in last Saturday's issue. I trust the resident medical officers of the various associations will now put forward all their exertions to emancipate themselves from the yoke of thralldom which they have been long labouring under and will loyally come forward and assist their brethren in exposing the iniquitous system of "sweating" which is no doubt being carried on with impunity in the greater number of these associations. All information should be addressed to Dr. Leslie Phillips without delay, which of course will be regarded as confidential. It is to be hoped also that the general practitioners will be fully alive to their own interests and communicate also all information bearing on the grievances they suffer from the working of Medical Aid Associations, and the injury they are causing both to the profession and the general public. I remain, Sirs, yours faithfully,

Oct. 18th, 1892.

A MEDICAL AID OFFICER.

## EXPERIMENTS ON ANIMALS.

To the Editors of THE LANCET.

SIRS,—Whether it was wise for the Church Congress to discuss the subject of animal experimentation or not it would be useless to enter into. The majority of the subjects-committee determined that such discussion should take place, and, this being the case, it was right that the best exponents of the two sides should be selected. For my own part, I believe that the meeting has done a great deal of good, for the experimental research has rarely or ever before had such a public hearing. The anti-vivisectionists, through an active and well-organised association, are working systematically throughout the country. At the Church Congress Art Exhibition a stall was erected for the distribution of their literature, and tracts were freely circulated even at the doors of the great Congress Hall. It seems to me that it is incumbent upon the members of the profession to be educated in this matter, and there should be some quick and sure way of imparting knowledge to those who wish to speak or write on this subject. It is useless for a man, unless he is well prepared with the subject and is an apt and ready speaker, to get up at an ordinary anti-vivisectionists' meeting. The speakers chosen are men well versed in the way of dealing with the gentler sex and with men of illogical minds. I believe that in no town in England at a public meeting, were the profession well represented, would the anti-vivisectionists carry the majority with them. The general public want to know the truth on this subject, but so far they have had only the opportunity of hearing one side.

I am, Sirs, yours truly,

Folkestone, Oct. 17th, 1892.

W. J. TYSON.

## AN IMPORTANT QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me a small space in your columns to call the attention of the medical profession to a question of principle involved in an inquiry which, I believe, is about to be entered upon by a subcommittee of the Manchester Medico-Ethical Association; and may I beg for an expression of your own opinion and the opinions of con-

sultants throughout the country who may consider it worth while to give the matter a moment's consideration? About the beginning of this year a gentleman called upon me and asked me if I would see a case with him in consultation. He gave me his name and address and I met him as proposed. I had vaguely heard that the practitioner in question had started in a somewhat humble way by keeping a dispensary; and I had some dim recollection of a complaint that one of our leading consultants here had met him in consultation. Having heard of these things, I had to decide before going to the consultation on what principle I must proceed. I found from the Register that the practitioner in question was a qualified member of the medical profession; I had never heard that his professional conduct had been publicly called in question; and there was no reason in our personal relations why I should refuse to meet him. I had also to remember that possibly the interests of a patient were involved. Some weeks afterwards I received a letter from a general practitioner residing in the same district as the gentleman whom I had met in consultation inquiring if I was aware of his neighbour's character and the opinion entertained regarding him by other members of the profession in their district of the city. Believing my correspondent to be friendly, I explained the grounds on which I had to decide the question of meeting such practitioners in consultation, and I had little doubt at the time that I was addressing a reasonable man. The next incident was a letter from my correspondent, containing a veiled threat to deprive me of any consultations that he could influence if I did not promise to decline to meet his neighbour in consultation in the future. I need not say what I replied to that letter. Yesterday I attended a meeting of the committee of the Manchester Medico-Ethical Association in my capacity of member of that committee, and to my surprise I was asked by one of the secretaries if I had any explanation to offer regarding my "case." I then learned that my former correspondent had brought a formal complaint against myself on the ground of the consultation referred to, and that I was in the position of defendant in connexion with some supposed breach of medical etiquette. That the committee of this Association are really serious seems to me to be proved by the fact that they have already, at the instance of the secretaries, nominated a subcommittee to try the case.

If you open your columns to the discussion of the principle involved in this matter I shall ask you to permit me on a future occasion to say something about the judicial functions of the Manchester Medico-Ethical Association. I will only say now that it is well known that their committee sought legal advice on the question of framing a "black list" and of prosecuting some member of the medical profession who was accused of underselling his neighbours by means of a dispensary, but that on economical grounds they decided not to proceed. I should also add that the deliberations of the subcommittees are supposed to be secret, and their conclusions are stated without reason assigned. Consequently one result of most of their inquiries is the spread of injurious gossip about somebody, originating in obscure hints from the irresponsibles who sit in judgment. One obvious question arising from this case is—Who is to be the inquisitor? If the consultant, how far is he to go in his inquisition as to the character and professional position of qualified members of the medical profession whom he is asked to meet? And that inquisition would also involve the question of when a member of the profession who commenced practice in a humble, perhaps dubiously ethical, fashion becomes white-washed and a respectable person whom anyone might be proud to meet in consultation. I do not think the answer to these questions far to seek; and but for the existence of a committee of a Medico-Ethical Association which plays at performing judicial functions, I do not think it would have ever arisen; but the matter is to me a real source of worry and annoyance, and I shall be grateful to you if you will insert this letter and either give expression to your own opinion of the matter, or permit any consulting members of the profession who may think it worth while to state their opinion on the principles involved.

I am, Sirs, yours faithfully,  
Manchester, Oct. 15th, 1892. W. J. SINCLAIR, M.D. Aberd.

#### "THE TREATMENT OF MYXŒDEMA."

To the Editors of THE LANCET.

SIRS,—As your annotation on the above subject in THE LANCET of Oct. 15th is apt to convey the impression that hyroid juice is difficult to obtain, and that it is dangerous

to give it by the hypodermic method, I wish to point out that this is not really the case. For the benefit of those who may wish to treat cases of myxœdema with thyroid juice I may mention that Messrs. Brady and Martin of Newcastle prepare an extract of the thyroid glands of freshly killed sheep in the manner described by me.<sup>1</sup> This extract, which consists of equal parts of thyroid juice, glycerine and 0.5 per cent. solution of carbolic acid, is prepared each week, and I am informed by the manufacturers that it is at present being employed in the treatment of some forty cases of myxœdema. Sufficient evidence has now been brought forward to show that thyroid juice can remove the symptoms of myxœdema. This was clearly shown in the discussion which took place on this subject at the meeting of the British Medical Association at Nottingham last July. It is remarkable how small a quantity of the thyroid juice can accomplish this. A gentleman who was recently under my care with typical symptoms of myxœdema had three drachms of thyroid extract—which are equivalent to the amount of juice contained in two whole thyroid glands—injected in the course of six weeks, when all the symptoms had practically disappeared. There can be no doubt about the efficiency of the remedy; but more extended observations are necessary to enable us to determine the most suitable dosage and the best means of administering it. Formerly I injected as much as twenty-five minims of the extract at a time, but now find that it is better not to give more than fifteen minims in a single dose. This dose of the fresh extract may be given twice a week, and if injected slowly in a part where the skin is loose and not exposed to pressure, with proper antiseptic precautions, unpleasant results rarely follow. The advantages of the hypodermic method are considerable. It is easily carried out, and only requires to be repeated twice a week at first, and afterwards an injection once a week or once a fortnight will maintain the patient in the improved condition. The main object of the treatment is to introduce the secretion of the thyroid gland into the circulation of the patient slowly and in as natural a condition as possible, and this end is attained by the hypodermic method.

I am, Sirs, yours truly,  
Newcastle-on-Tyne, Oct. 19th, 1892. GEORGE R. MURRAY.

#### "REMOVAL OF LEAD FROM THE EAR BY THE USE OF METALLIC MERCURY."

To the Editors of THE LANCET.

SIRS,—I am not unprepared for the criticism of Mr. Ryan and Dr. Barrett in your issue of Oct. 14th. Several chemists have already expressed their surprise that "quicksilver" should have acted in the way I described. The statement of my critics that the syringe was not used prior to the employment of the mercury is "an inference, not a fact." We in this country well know the utility of syringing in cases of foreign body in the ear. In the present case syringes with nozzles of different curvatures were several times applied, with the head of the patient in different positions, quite unavailingly. Yet it is a significant consideration that in the first employment of the syringe after the mercurial application the piece of metal escaped with ease. As over six weeks had elapsed since the primary injury and the patient had been most judiciously treated, inflammatory swelling had subsided, and no rational person who saw the firm impaction of this piece of metal could have attributed it to inflammatory swelling. The piece of lead I used for my preliminary experiment was that thin short lead used to wrap round fishing lines. I have no means here of ascertaining its actual composition, but as the mercury rendered it brittle it was doubtless an alloy and not pure lead. The experiment was a rough one indeed and lacking in scientific accuracy, but it afforded me a hint which the extreme urgency of the case compelled me to at once act upon. I believe that the firm impaction of the metal was largely due to fine processes of it passing into the anatomical foramina and canals. After the quicksilver had been some hours in the ear the patient noticed it running into his throat, as though the mercury had diminished the size of the prolongation of metal in the Eustachian tube. It is possible, too, that the fine processes may have been chemically altered by prolonged contact with the gases and salts of the serum and pus at the temperature of nearly 100° F. I do not gather that my critics observed this

<sup>1</sup> Brit. Med. Jour., Oct. 10th, 1891.

temperature or the possibility of chemical changes in their experiments. On reading their article I at once wrote to the patient. He replies that the metal was "plumber's solder, lead mixed with tin." This settles the question between us, for it is this mixture that my critics found most affected by mercury in their experiments. The original piece of metal is in the custody of the College of Surgeons, and I should be sorry in any way to mutilate it. During the past fortnight there has been extracted from the nose of this patient, by means I need not occupy space in describing, two irregular masses of metal, obviously of the same origin and composition as the metal in the ear. These I have exhibited to Sir William Dalby, who has taken great interest in the matter, as he himself once removed impacted plaster of Paris from the ear by chemical solution. Anyone can see them who cares to do so, and I will in the future have them examined. I was not aware that the prevalent general commercial impurity extended so largely to lead, but when we consider the number of mixtures in use the full consideration of the question becomes purely a chemical one of some complexity. I am convinced of the efficacy of the mercury in the case related, and am content to leave the explanation of undoubted fact in the hands of others. If I have committed any errors in the relation of the case, such errors are purely those of inference, not of fact.

I sympathise with my critics in their efforts to extract the shot from the ear, and must confess that the failure of the mercurial method has disappointed me. I am informed that the composition of shot and ball differs also very widely, and a chemical examination of the metal in their case is as needful as in mine. It would be interesting to know if they have employed the syringe, especially one with a curved nozzle, while the ear is in a dependent position. As they can see the shot "lying on the floor of the canal," I should have expected this to succeed.

In conclusion, I will thank my Australian *confrères* for the interest they have taken in this case, for their ingenious explanation of an undoubted difficulty, and for the courtesy and kindness of their criticism.

I am, Sirs, yours truly,

A. MARMADUKE SHEILD, M.B. CAMB., F.R.C.S. ENG.  
Stratford-place, W., Oct. 10th, 1892.

## CORROSIVE SUBLIMATE INJECTIONS IN LUPUS.

To the Editors of THE LANCET.

SIRS,—Dr. Cowan Lees' suggestive remarks on the treatment of inoperable malignant neoplasms by the bichloride of mercury in oil in THE LANCET of Oct. 15th, induces me to refer to the treatment of lupus in its initial stages by the subcutaneous injection of corrosive sublimate in 1 per cent. aqueous solution, five or six minims of this being injected into the infected part with a suitable syringe. Three years ago I showed a patient before the Northumberland and Durham Medical Society affected with hypertrophic lupus of the left ala nasi, who had undergone the treatment and eventually recovered with only slight loss of tissue. In another case not of a hypertrophic character the patient recovered after a single injection, the site of the lesion being also in the left ala. This is now perfectly sound, but the seat of a round perforation and slight atrophy. In another case where the lupus was situated just under the left ala nasi, extending to the floor and slightly on to the septum naris, with considerable swelling of surrounding parts, three injections sufficed to cure, little recourse having been made to other remedies. It will be observed that I use a stronger solution of this salt than Dr. Lees, but it is the strength proposed by the author of the treatment, whose name I cannot for the present remember. The injection causes very considerable reaction with swelling of the tissues now and then, going on to the formation of abscess. As to its merits, as I have shown in lupus in its early stages, it is of great value, and I have adopted it as a matter of routine when I meet with suitable cases.

I remain, Sirs, yours faithfully,

WM. ROBERTSON, M.D. Glas.

Newcastle-on-Tyne, Oct. 10th, 1892.

## AN UNUSUALLY THIN SKULL.

To the Editors of THE LANCET.

SIRS,—The following case may be of interest to many, not only on account of being curious, but also from its bearing in a legal aspect.

On Saturday, Oct. 1st, at 5.15 P.M., I was called to see G. B—, labourer, aged about forty-five, who, it was stated, had been fighting. I found him insensible and suffering from fracture of the base of the skull, evidenced by bleeding from the ear; but with very careful examination both at the time and on the following day (Sunday) I could find no marks of violence whatever. He died on Monday morning at 1.15 without having recovered consciousness, thirty-two hours after the fight. I subsequently made a post-mortem examination and found two very slight, scarcely perceptible bruises on the point of the chin, as if caused by knuckles. On opening the cranium I found the base of the middle lobe of the brain lacerated by the plate of bone forming the glenoid fossa being driven in by the condyle of the inferior maxillary bone and a fracture extending across the base of the skull, and on the left side across the squamous portion of the temporal bone and the left parietal; but the bone of the left side of the head (parietal and squamous temporal) was nowhere thicker than the thin plate of a scapula, and the petrous portion of the right side was so friable that I crushed it quite easily with my finger and thumb. The man who is alleged to have caused his death is stated by several witnesses only to have struck him once, and was far too drunk to have hit very hardly.

I am, Sirs, yours faithfully,

FRANK OLDFIELD, L.R.C.P. Edin.

Boyson-road, S.E., Oct. 17th, 1892.

## PROPAGATION OF EPIDEMICS.

To the Editors of THE LANCET.

SIRS,—Adverting to the letter from Mr. Sherman Bigg in THE LANCET of Oct. 8th, under the heading, "The Propagation of Cholera," it might be interesting to quote the following passage from the Oration delivered before the Medical Society of London in the spring of 1820—viz., "I am aware the expression 'pestilential constitution' has been objected to on the ground of its involving the supposition of a latent undefined state of the air which it has been stated is nothing more than a creature of the fancy. But if we consider that the phrase is used to denote an ultimate fact or that state of things when the whole complication of causes which conspire to originate or propagate pestilence takes effect it is not unphilosophical, and when such men as Hippocrates, Sydenham, Bacon and Russel thought it necessary to take such a fact or principle for granted. I do conceive that we of the present day who have not witnessed what came under their individual observation are not at liberty to reject it because we cannot explain the cause. I therefore assume that during the prevalence of every pestilence there is a peculiar state of the atmosphere which—whether it be called corruption, as it is by Mead, or pestilential constitution, as by others; whether it be the absolute or only the concurring cause; whether it be a principle or only a quality—is no more necessary to be known in reasoning upon its effects than a knowledge of the gravitation, principle or power is essential to the proof of the existence of the law."<sup>1</sup> It seems legitimate to maintain that there may be such a condition of the atmosphere as that referred to above having a subtle affinity for the propagation of contagium and equally a pernicious effect on the resisting power of animals (man or otherwise) to become infected by that particular contagium. Otherwise, is it possible to understand how it is that some diseases which may be endemic in a locality pass from the sporadic to the epidemic type, and yet under continuous local conditions revert to their original character? Probably it may be that the contagium of a disease increases in such "a peculiar state of the air," thus leading to an epidemic, and then diminishes as it itself exhausts the pestilential pabulum or "constitution."

I am, Sirs, yours faithfully,

Sanitary Institute, Oct. 16th, 1892.

C. E. MACNAMARA.

## "NOTIFICATION OF INFECTIOUS DISEASE."

To the Editors of THE LANCET.

SIRS,—Dr. Corfield cites the Local Government Board as having ruled in accordance with his views on this subject, and one can only say, "pity 'tis 'tis true." I agree nevertheless with Dr. Goodhart in thinking that, whatever the letter of the

<sup>1</sup> Vide Hancock on the Laws of Pestilence, pp. 81 and 82.

Act may be, it cannot have been its intention to make each one of a number of medical men who may have seen an infectious case notify the same, such an obligation being neither in accordance with reason.—Dr. Corfield admits that "he does not want more than one certificate of one case"—nor with economy in the expenditure of rates. The word "every" in the quotation from the Act, commencing "Every medical practitioner" &c., may obviously be read as implying one of two things: (1) a provision that the Act shall not be frustrated by one man not notifying his infectious cases; or (2) that every infectious case must be notified by each medical man who may see it even when two or three do so. The latter is certainly a strained interpretation and, with all due respect to Dr. Corfield, the authority that "every month sanctions payments to two or three medical men for certifying a single case" in my opinion by so doing opens the way to confusion in its returns and sanctions an unnecessary expenditure of public funds.—I am, Sirs, yours faithfully,

Hull, Oct. 15th, 1892. G. F. ELLIOTT, M.D. Oxon. &c.

## WILLIAM HARVEY AT SUTTON PLACE.

To the Editors of THE LANCET.

SIRS,—The conjecture in your leading article of Sept. 24th, that the great William Harvey was sent for to Sutton Place, near Guildford, to attend a grandchild of the Countess of Arundel in 1619, is quite correct. I happen to have in the press a volume giving a history of the house, which has been for some time in the occupation of my family. When my father was making some alterations in 1875 a deed was found executed by Anne Countess of Arundel, April 13th, 1621. She was in occupation of the house during the absence abroad of the owner, Sir Richard Weston, who was a distant cousin of the Howards. Undoubtedly William Harvey stayed in the house, as did many other historical personages from time to time:—Henry VIII., Catherine of Aragon, Wolsey, Thomas Cromwell, Queen Elizabeth and her court, and many others.

I am, Sirs, yours faithfully,  
FREDERICK HARRISON.

Westbourne-terrace, W., Oct. 14th, 1892.

To the Editors of THE LANCET.

SIRS,—I see in your issue of Sept. 24th that the celebrated Dr. Harvey is mentioned as having been called in from London to attend a child at Sutton Place near Guildford. Your article is very interesting, as I am now the owner of the property through my mother, who was a Weston. Perhaps you will be interested to hear that the history of this house is about to be published soon by Macmillan, with many illustrations &c.

I am, Sirs, yours truly,  
F. H. SALVIN.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

### The Food of Seamen.

At a late meeting of the Tees Port Sanitary Authority the medical officer drew attention to the improper nature of the food served to seamen. In a case where he was present he saw that a crew was supplied with food consisting of "biscuits running alive and stinking meat." It was agreed to bring the matter under the notice of the Local Government Board.

### Durham University Intelligence.

Amongst the scholarships in arts, as the results of the late examinations issued on Saturday last, Mr. M. A. Archdall has gained the Medical Scholarship, value £100.

### Relief Fund in Newcastle for the Cholera in Hamburg.

A meeting has been held in the Mayor's Chamber, Guildhall, for the purpose of raising a relief fund for the cholera sufferers at Hamburg. The meeting was very well attended and the sum of £300 was subscribed in the room. While on the subject of cholera I may mention that the answer of the Local Government Board to the memorial of the Tyne Port Sanitary Authority came up for consideration at the last meeting of the Tyne Improvement Commission and the answer, in short, refused to grant the Tyne Sanitary Authority increased quarantine powers in case of cholera. It was stated at the meeting that they ought to

have larger powers to control the men and their movements when they came into the river a few hours after leaving an infected port. It was the general opinion that the medical officer had discharged his duties well with his limited powers, but that it was impossible for him at present to trace hundreds of sailors after they had left their ships and were dispersed in various parts of the country, and at present they were in the position that if there was a probability of cholera being introduced they had to apply to an authority that knew very little about them. It was agreed, in view of the great importance of the subject, that a special meeting of the Tyne Commissioners should be held shortly.

### Ambulance Work in the North.

An important meeting connected with ambulance work at the Elswick Works was held last week. Some idea of the interest taken in the ambulance classes in these great factories may be formed from the fact that last session 230 students entered for instruction, the greater number of whom completed the full course of lectures and instruction under Mr. R. C. Clark Newton, of this city, who was highly complimented on the success of his teaching and work.

### Sheffield Medico-Chirurgical Society.

The opening meeting of the session took place on Oct. 13th, when Mr. Snell delivered the inaugural address. Having alluded to the establishment of the *Sheffield Medical Journal*, the President proceeded to consider some of the lessons which he thought could be drawn from a glimpse at the life and work of the late Sir W. Bowman. It was, Mr. Snell said, Sir W. Bowman's habit of exact observation that placed him early in his career among the leading histologists of this century. Reference was made to his influence on ophthalmic surgery, which had been more the result of his oral teaching than of his writings. The distinct personality of the man, his dexterity as an operator, the charm of his manner were all alluded to, but the lecturer said that he was essentially an accurate and close observer, and it was on those characteristics that his enduring reputation rested. The method of Zsigmondy as mentioned by Dr. Lauder Brunton was referred to, and from this Mr. Snell passed on to speak of an aspect in the work of our societies which he thought was worth following out—he meant the after-histories of cases. The time at which a case was recorded might or might not be the most interesting or most important. He believed the Ophthalmological Society was undertaking some such work. A study of the records of the Society had shown him that he had records of the after-histories of many of the cases he had at different times either related or shown before the Society. Some of these he proceeded to sketch. One was the case of a girl with recurrent third nerve paralysis associated with migraine. At the time this case was published (in 1884) only two other cases of the kind had, he believed, been published. He had followed up this case, and at the present time the attacks of migraine persisted and were still accompanied with ocular palsy. Allusion was also made to cases of Graves' disease, to one of sarcoma of the eyeball, which had supervened after sclerotomy for glaucoma after a long interval, and whilst the interior of the eyeball could be illuminated there had been no growth detected. Mr. Snell also gave further particulars of a series of cases of extra-genital syphilis, some of which had already been recorded. Remarks were made as to the lessons to be learnt from these cases. The possibility of ulcers in different parts being syphilitic chancres should be borne in mind. The cases mentioned had come under notice in the ordinary course in an ophthalmic practice; the general surgeon had the opportunity of gaining a far larger experience from a much wider class. After referring to published statistics as to the frequency of non-venereal syphilis, Mr. Snell concluded an interesting address by saying that he hoped he had done something to show that the after-histories of cases were fraught with interest and value if founded on close and accurate observation.

### Medical Men as Magistrates.

Dr. Page and Mr. H. W. Newton of Newcastle-on-Tyne have both been placed on the Commission of the Peace for the county and city of Newcastle-on-Tyne. Newcastle has always had in the ranks of the profession men of public power and importance, and it is so still. Mr. Newton has been mayor and may possibly be so again. There is a great public rôle for medical men, though it should be one well above the rough level of mere party strife.

At a recent meeting of the rural sanitary authority at

Kirkby Stephen it was stated that the contracts had just been let for the construction of extensive waterworks for a group of villages in the Eden Valley.

Newcastle-on-Tyne, Oct. 10th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Aberdeen Royal Infirmary.*

At a meeting of directors held last week, Dr. Scott Riddell, assistant surgeon, was specially attached in that capacity to Professor Ogston, and it was resolved to appoint a second assistant surgeon at the next meeting of directors on the 26th inst. Dr. Riddell is assistant professor of surgery in the University. Candidates for the vacant post are already in numbers in the field and are canvassing eagerly.

### *Health of Aberdeen.*

The death-rate in September was 16.36 per 1000, as against 15.84 in August and against 16.51 in September last year. There had been 307 cases of measles with 4 deaths, as against 63 with 5 deaths in the previous month; scarlet fever, 121 cases with 3 deaths, as against 86 with no deaths in the previous month; whooping-cough, 16 cases and no deaths, as against 45 cases and 8 deaths in the previous month; diphtheria, 6 cases; typhoid fever, 10 cases with 3 deaths; and typhus fever, 3 cases. The average daily number in the City Fever Hospital was 78.9. The medical officer of health again drew attention to the great and urgent want of increased accommodation at the hospital. He said it was absolutely necessary that immediate steps should be taken to provide better accommodation for the nurses, and the Public Health Committee decided to do as the medical officer suggested. Last week 356 cases of measles and 73 of scarlet fever were reported—an increase on the week of 192.

### *Aberdeen University: Dr. Hamilton on Asiatic Cholera.*

At the opening of the winter session in medicine at Aberdeen last week, Professor Hamilton delivered an impressive address on Asiatic Cholera. He first complimented the sanitary authorities for their vigilance in warding off any possible source of contagion from these shores. He then traced the history of the last epidemic from its source in India westwards, showing how it followed the lines of steamboats and railways, and explaining how an epidemic which used to take years to spread from India to the Atlantic, could accomplish the distance now in three months and a half. Cholera is essentially a dirt disease and is carried by dirty people to dirty places. The Holy Well of Mecca is a veritable hotbed of the malady. The disease in Hamburg was traceable to the pollution of the Elbe and Alster, from which the drinking-water was drawn. The famous case of East London and the Lea in 1866 was next quoted, and the lecturer finished by criticising the Aberdeen water-supply and pointing out dangers which might arise in the event of an outbreak of cholera.

### *Unwholesome Food in Aberdeen.*

The sanitary inspector of Aberdeen, in his report as to the inspection of unwholesome food, states that during the month of September he seized 1568 lb. of beef, 850 lb. of fruit, 1085 lb. of wet fish, and 2016 lb. of smoked fish, all of which had been destroyed either by the order of the magistrates or with the owner's consent.

### *Proposed Hospital for Turriff, Aberdeenshire.*

At a meeting of the Turriff District Committee of the County Council, the clerk intimated that it was practically impossible for them to get their fever patients treated at Chalmers' Hospital, Banff, and it was formally agreed to remit to a subcommittee to act along with the police commissioners of the burgh of Turriff in selecting a site and obtaining plans of a hospital to be built at or near Turriff.

### *The Glasgow Societies.*

The working season in the various societies has begun. The Medico-Chirurgical Society was opened last week with an address from the President, Dr. Joseph Coats, on the Infective Theory of Cancer. The first meeting of the Pathological and Clinical Society was held on Monday last, Dr. A. Napier showing two cases of myxœdema, in one of which remarkable improvement, which is maintained now three months after cessation of treatment, had followed the subcutaneous injec-

tion of an extract of sheep's thyroid; the second was a well-marked case, in which the same treatment was about to be adopted. Dr. R. M. Buchanan showed some very beautiful microscopic sections of thyroid gland from a fatal case of myxœdema. Drs. S. Gemmell and Lindsay Steven showed an aneurysm of the posterior wall of the transverse part of the arch of aorta in which there had been a remarkable absence of physical signs. Dr. A. E. Maylard showed a traumatic aneurysm of the radial artery which had been removed by excirpation.

### *Population; Public Health; Glanders.*

The medical officer of health for Glasgow has just made his calculation of the population in Glasgow proper for this year based on the number of tenanted houses—namely, 139,038. After deducting 1½ per cent., representing houses not occupied, and multiplying by 4.778 (the average number of inhabitants per house in 1891), the population was estimated as 654,361 persons. Adding to this inmates in institutions, harbour population &c., the population is estimated as 667,531. The death-rate for the fortnight ending Oct. 1st was 18.5, as against 18 for the previous fortnight. Since notification of "British cholera" and "choleraic diarrhoea" became compulsory on Sept. 22nd, twenty-one certificates of the former disease and fourteen of the latter had been sent in, but in none of the cases was there the slightest ground for suspecting a choleraic element in the strict sense of the term. The medical officer of health reports a case of glanders in a man. The unfortunate patient became ill on Sept. 20th and died on Oct. 3rd. He had been employed as a foreman in the service of the Glasgow Tramway Company. Glanders had existed for some time in the stud under his charge, and he believed that an infected animal had coughed or snorted in his face.

### *Fees for Attendances in Street Accidents.*

Some time ago the municipal authorities determined to allow a small fee for services rendered to the subjects of street accidents, especially in cases in which a practitioner had been called by the police. But lately some accounts have been presented not relating to street accidents, and as the four or five accounts rendered per month were felt to be a burden by this wealthy corporation, it has been determined to repudiate such accounts unless the doctors claiming certify that they have made every reasonable endeavour to recover the accounts from the patients or their friends and have failed. As Glasgow has quite the average number of accidents occurring in a large city, it is evident that as only "four or five" accounts have been sent in monthly, the medical men of the city have been doing practically their usual amount of gratuitous and often thankless work. As each individual fee in such cases is small, it is probable that few doctors will put themselves to the trouble of first "worrying patients and their friends." The authorities will have the satisfaction of telling their constituents in November next that they have effected a saving of "four or five" doctors' fees per month. But what a petty and undignified economy for the city of Glasgow!

### *Opening of the Medical Schools.*

This week sees the various medical schools in full swing. In the University the inaugural address was delivered by Professor Cleland in the Bute Hall. The ladies from Queen Margaret's College, thirty or forty in number, present in virtue of the absorption of their college by the University, were seated in one of the side aisles. [We publish part of Professor Cleland's lecture in another column.] At Anderson's College Medical School the session was opened by Professor W. L. Reid, who took for his theme the Life of Smellie, from which many lessons were drawn of courage, perseverance and devotion to science for its own sake. St. Mungo's College was opened with an address from Professor McVail, who first of all expounded and criticised the new five years' curriculum, devoting the remainder of his lecture to consideration of the questions: "Do we know disease in all its variety better than our predecessors, and can we deal with it more successfully than they could?" to which he replied most emphatically in the affirmative.

### *Western Infirmary.*

At a special meeting of the managers of the Western Infirmary yesterday Dr. Macewen was unanimously appointed one of the visiting surgeons in room of the late Sir George Macleod.

### *Professor Macowen's Opening Address.*

This was given on Wednesday, in the Bute Hall of the

University. Professor Macewen first warmly thanked those who had supported him and so enthusiastically congratulated him in connexion with his appointment to the chair of Surgery. He then referred in touching terms to his long connexion with the Royal Infirmary, speaking most gratefully of the services rendered to him by his nurses, his house surgeons, his colleagues and the directors of the infirmary. In the latter part of his lecture he recorded his early impressions of his teachers in the University, and referred to some of the distinguished men who had graced the various chairs in times past. His reference to the Hunters contained at least one good story. He said:—"However the Londoners may have been wanting in appreciation of John Hunter's genius while he lived among them, they have amply compensated for it by the care they have since bestowed upon his magnificent museum, to which they are constantly adding, and by the establishment of 'Hunterian Orations' the memory of his achievements is annually revived. Contrast this with what is done in Glasgow to perpetuate the memory of these two great men. The public have almost forgotten their name, and this is even the case at their birthplace, Longcalderswood, to which, in company with Dr. Mather, I made a pilgrimage in search of Hunter's house. When the question was put to one old lady as to the whereabouts of the house which used to be inhabited by the Hunters, she naively answered in the Scotch fashion: 'What hae *they* been daen that ye're speerin' for *them*?'"

Oct. 20th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The New Lord-Lieutenant*

THE Royal College of Physicians has presented an address of welcome to the Lord-Lieutenant on his arrival in Ireland. They assured his Excellency that they were now ready, as in the past, to afford to Her Majesty's Government their hearty assistance in all matters relating to medicine and the health and welfare of the people.

### *Vice-Regal Appointments.*

The following is a complete list of those attached to the Lord-Lieutenant's household:—Physician in Ordinary, Christopher Nixon, M.D.; Surgeons in Ordinary, Richard F. Tobin, F.R.C.S., and Arthur Chance, F.R.C.S.; Surgeon Oculist, A. H. Jacob; Surgeon to the Household, T. Nedley, M.D.; Surgeon Dentist in Ordinary, Daniel Corbett, M.D.

### *Health of Dublin for September.*

The death-rate was 2.14 lower than the mean rate for the previous ten years. As compared with the preceding month there was a very great decrease in the mortality caused by measles, and the epidemic may now be considered as at an end. Owing to the prevalence of cholera in certain parts of the Continent precautions were taken to prevent the disease from invading Dublin. Great attention was paid to the cleansing of the streets and the flushing of sewers. About £130 worth of disinfectants were used in the flushing of courts, alleys, lanes &c.

### *Royal University of Ireland.*

The graduates' third annual conversazione will be held in the University buildings by permission of the Senate on the evening of Conferring Day, the 28th inst. The programme will include a concert, scientific exhibitions and demonstrations, and a military band will attend.

### *The Admission of Lady Students to the South Infirmary, Cork.*

The trustees have adopted a resolution permitting lady students to attend clinical instruction at this hospital, and the minutes of said meeting were signed on the 14th inst. Some of the trustees, however, consider that Rule 26 has been broken, and after an animated discussion for and against the admission of lady students, it was determined to hold another meeting of the board to consider the following notice of motion:—"That at the next board meeting the resolution of the 15th ult. relative to the admission of a lady applicant and other females as students to the clinical teaching of this hospital be rescinded on the grounds that such combined instruction of the sexes is prejudicial to the good working of the institution and has been found to work un-

satisfactorily in other hospitals." I believe I am correct in saying that there is no by-law of the infirmary which would prohibit the admission of lady students for clinical instruction, and that their application for admission is merely an act of courtesy on their part, which some of the trustees appear to be unable to appreciate.

### *Proposed Cottage Hospital for Bray, Co. Dublin.*

The medical officer of health and the consulting sanitary officer have recommended to the Bray Town Commissioners the erection of a cottage hospital for the use of the township, as in the event of an outbreak of cholera there is at present no proper place available but the Loughlinstown Workhouse Hospital, which is situated at too great a distance for patients suffering from cholera to be removed there. If not required now for the cholera it would be at all times available either for accidents or for epidemic diseases. The report has been referred to the Public Health Committee of the township.

### *American and Irish Surgery.*

Mr. N. Grattan, F.R.C.S. Edin., of Cork, who has just returned from the United States, has been elected a corresponding member of the Orthopædic Section of the New York Academy of Medicine. He is the first Irish surgeon who has received this honour. He gave a demonstration of his method of treating deformities before a large meeting of the Orthopædic Association at the Hospital for Cripples, Twenty-fourth-street, New York. Afterwards he gave a second demonstration to members of the profession at the Post-Graduate Medical School and Hospital. On Wednesday, Sept. 24th, Mr. Grattan gave the opening lecture and demonstrated his method of operating at the clinic of Dr. Sayre, Bellevue Hospital and Medical College. Last year the honour of giving the opening lecture was accorded to Sir William Mac Cormac, who is also a distinguished Irish surgeon.

### *Royal College of Physicians of Ireland.*

The annual meeting of the Fellows was held on St. Luke's Day for the purpose of electing a President and other office-bearers for the ensuing year. Dr. Finny's second year of office as President having terminated, the Fellows elected Dr. W. G. Smith as his successor. Dr. Smith is physician to Sir Patrick Dun's Hospital, and Professor of Materia Medica in the Medical School of the University of Dublin. Dr. Lombe Atthill was again re-elected representative of the College on the General Medical Council, and Dr. J. Moore, late registrar, has been succeeded by Dr. G. P. Nugent. At the same meeting Mr. Michael F. Cox, senior physician to St. Vincent's Hospital, was elected to the Fellowship of the College. Dr. Samuel Gordon has presented the College with a half-length portrait of its founder, Dr. John Stearne.

### *Hospital Dinner.*

The medical staff of St. Vincent's Hospital and some friends dined together at the Shelbourne Hotel on Tuesday evening, the first of a series of annual reunions.

### *Dispensary Medical Officers' Grievances.*

The Chief Secretary has refused to receive a deputation on the subject of the grievances of Irish dispensary medical officers on the ground that there would be no prospect of considering the necessary legislation in the approaching session of Parliament.

Oct. 18th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *High Altitudes and Health.*

A FEASIBLE explanation of one of the factors going to make up the sum of causes which brings about that often-marked amelioration in the health of phthisical persons who have recourse to the high altitude treatment would appear to be emphasised by the communication made by M. Egger at the recent meeting of the Swiss Society of Natural Sciences held at Bâle. This observer, taking the Alpine station of Arosa as his example, came to the same conclusion as Viault, who found that after a certain residence on these elevated plateaux the red corpuscles of the blood increased to a very notable extent. After two or three weeks' sojourn at an altitude of 1890 metres M. Egger found in a number of individuals an augmentation of the red discs to the extent of 1,500,000 per cubic millimetre. Now was this increase in the capillaries only apparent; it was real

and found to be the same in the larger arterioles. Neither was it due, in M. Egger's opinion, to any desiccation of the tissues by the dry atmospheric influences of the mountain. These observers further note that the red discs again diminished in quantity after a certain stay in the plains. M. Egger adds that he believes one of the causes of mountain malaise to be due to a relative anæmia of the organism, which latter must adapt itself to surrounding conditions. The benefit thus derived by tuberculous subjects from a stay on a mountain top on the one hand, and the anæmia which is an almost constant premonitory as well as a later sign of tubercular lung mischief on the other, appear to lend support to the theory that there is an antagonistic action between the tubercle bacillus and certain other embryonic elements, and would seem to say much in favour of the views of Pasteur's disciples.

#### *Intra-uterine Injection of Glycerine.*

The injection of glycerine into the rectum has for some years been current in practice, and it is recognised in certain conditions to be a very convenient and efficient method of administering an enema. It strikes me as strange that a substance so efficient in emptying the rectum should until now have been put to comparatively few trials in emptying the uterus of its contents, for *a priori* it seems a likely agent for this purpose. M. Pelzer records some observations made in the latter direction, and speaks favourably of intra-uterine injections of glycerine for the inducing of necessary premature labour as well as in cases of insufficient uterine contraction. His method of procedure is as follows: He takes a syringe of the capacity of 150 grammes, or a little over four ounces, and, having filled it with pure glycerine, he attaches it, through the medium of a gutta-percha tube, to a perforated sound. Having cleared the apparatus of air in the usual way, he introduces it into the uterine cavity between the posterior wall and the membranes to the fundus of the organ. The glycerine is then injected and the pelvis elevated to prevent its too rapid escape. In a very brief space of time energetic contractions are set up. The effect of the glycerine is due in part to its mechanical action in separating the membranes from the uterine wall and in part to its chemical affinity for water, by virtue of which some of the amniotic liquid is abstracted, which in turn contributes to a further detaching of the membranes. On the whole M. Pelzer was pleased with his results and suggests glycerine as worthy a further trial in obstetric practice.

#### *General Education of Midwives.*

Whilst in England the whole position and status of the midwife, to say nothing of her education, general (if any) or professional, is one of doubt and uncertainty, if not worse, and while schemes for her improvement off or on the face of the earth appear to be matters of sore contention, here in France it must be admitted the practice of midwifery by women as well as the position and professional scope of the midwife are on very clearly defined lines, the study of which by those interested for or against the Bill now or lately before the Westminster Parliament might well repay. Doctors' fees for obstetric work in France and its large towns are well known to be high, by comparison with those in England; but the explanation is not always added, which is that almost all the cheap midwifery here is done by the "sage-femme" or midwife, and those who are unable to afford even the services of the professional midwife have recourse to the lying-in wards attached to mostly all the general hospitals or to the maternity hospitals. The "sage-femme" of Paris thus occupies an intermediate but distinct professional position, and no complaint is ever made that she interferes with or encroaches on the doctor's sphere, to whom, however, she must always have recourse in cases of difficulty, for she is not allowed by the law to perform obstetric operations or use any instruments. It was only the other day that special permission was accorded to her to use perchloride of mercury in vaginal douches. Her professional education is well looked after, for she must do the curriculum and pass the examination prescribed before her diploma issues. As to her general education, the following letter from M. Bourgeois, the Minister of Education, to the rectors of the various faculties shows that in that respect also she will compare somewhat to the disadvantage of her English confrère:—"Monsieur le Recteur,—My attention has been called to the increasing inconvenience caused by the deficiency in primary education too often betrayed by the candidates for the diploma of midwife. .... For the future the possession of a certificate of primary study

will in no sense exempt candidates for the midwifery diploma from the preliminary examination instituted by the decree of Aug. 1st, 1879. Be good enough to inform the deans and directors in your academical centre of this division, and invite them to place it within the knowledge of those interested."

#### *Statues of Eminent Doctors.*

I cannot recall to mind where in England there is to be found a statue to any of the good and great men in our profession who have an undoubted claim on humanity, unless it be the single exception of Harvey's in Folkestone. Not so throughout France. Paris alone has statues to Broca and others, and will shortly have one to Ricord, for which the President of the Republic has approved the sanction of the Prefect of the Seine authorising the erection of the statue in one of the public places of Paris. To-morrow also will be inaugurated at Morlaix the bust of Depaul, formerly the well-known professor of obstetrics at the University of Paris. Oct. 19th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *The Cholera in Germany.*

THE number of cholera cases officially reported from Hamburg last week was 101, the number of deaths twenty-seven. The Imperial Office of Health has been for some time past investigating the behaviour of cholera bacilli on and in various kinds of fruit, beverages, tobacco, sweetmeats and fish, and will publish the results of the experiments soon.

#### *Professor Virchow's Inaugural Address as Rector of Berlin University.*

Professor Virchow was formally installed as Rector of Berlin University last Saturday, and delivered an address to the students and professors, in the course of which, while gratefully acknowledging the valuable results of classical education in the past, he declared that "the golden triad of mathematics, philosophy and natural science" must be the main staple of high education in future. I quote the following sentences as of special interest for medical men. "No schoolboy will be the worse for being able to name and distinguish a certain number of plants, animals or stones. But the essential discipline should consist in the training of the senses, especially those of sight and touch. At present we have to complain that a large number of our hearers have no exact knowledge of colours; that they make false statements about the form of the things they see; that they show no understanding for the consistency of bodies and for the nature of their surfaces. Nothing should be easier than to develop accuracy of judgment regarding colour and form, if not only observing but also simple drawing and painting were taught. Everyone can make use of such knowledge; for the medical man it is of the greatest value, as the diagnosis of the most important conditions not unfrequently depends on it. The experimental natural sciences, especially physics and chemistry, are also indispensable for school instruction, for they show better than anything else the genetic and causal connexion of processes, and prepare for the systematic study of the more abstruse problems of biology."

#### *Surgeon-General Dr. Mehlhausen.*

In accepting Surgeon-General Mehlhausen's resignation as Director of the Charité, the Emperor appointed him surgeon-general "at disposal," and bestowed on him the Star of the Crown Order of the second class. The decoration and the document accepting his resignation were conveyed to him by the Minister of Educational, Ecclesiastical and Medical Affairs. The Society of the Physicians and Surgeons of the Charité have elected him honorary president and presented him with an album containing photographs of all the former and present members.

#### *The New Director of the Charité.*

Surgeon-General Dr. Hermann Schafer, Surgeon-General Mehlhausen's successor as medical director of the Charité, received his medical education in the Berlin establishments for the training of medical men for the army. He graduated in 1864, passed the State examination in 1866, and served for some time after the French war in the Charité. He afterwards served in the garrison in Hanover. His last post was that of medical officer to the 17th Hussars at Brunswick,

where he was also Physician-in-Ordinary to the Prince Regent, Prince Albert of Prussia. Except a booklet on the care of children—which appeared in 1878—and lectures on various hygienic questions—which he published in 1884—all his medical writings have appeared in the *Militärärztliche Zeitschrift* (*Military Medical Journal*). Their subjects are the transference of small-pox by skin-grafting in the preliminary stage of the disease, Weil's disease, purpura &c.

#### Medical Incomes in Berlin.

From the income-tax returns recently issued the profession of medicine in Berlin would not seem to be one to be followed by men ambitious of financial success. There are 1747 medical men in this city—nearly half the profession—who make less than £150 a year. Only 250 make £400, and 170 more than £500. If this is the state of matters in the capital, what must it be in the country?

Berlin, Oct. 18th

## Obituary.

### DR. PIETRO PELLIZZARI.

ON Sunday, the 2nd inst., the Florentine school lost this able and accomplished teacher and consultant after an illness of several months' duration. Dr. Pellizzari held the chair of Dermosyphilopathy in the Istituto de' Studi Superiori, and in connexion with it had charge of the wards set apart for syphilitic and cutaneous diseases in the hospital of the S. Maria Nuova. In both capacities, as an expounder of system and as a clinical instructor, he had rare gifts and accomplishments, the combination of which rendered him the most popular and the most effective teacher and examiner in his special *métier* throughout Italy. Students from all parts of the peninsula flocked to his prelections and clinique, while for years he had established among his compatriots the highest position as a practitioner and consultant. "The Italian Ricord" was a title he was well and widely known by. His youth, like that of so many other Italians who have risen to professional distinction, was spent in an atmosphere of revolution, and in sympathy with the cause of his country's independence and unity he served in the ranks of the volunteers in more than one patriotic rising. The consummation of a "united Italy with Rome for capital" once achieved, he threw himself with ardour into medical study—ardour all the more intense for the interruption so nobly incurred—and speedily rose to the front rank in the speciality which became his own. He was a powerful advocate of the disposal of the dead by cremation, and had indeed for many years been President of the "Società dei Cremazione" in Florence. In the terms of his will, and in keeping with his life-long precept, his body was on the 4th inst. reduced to ashes in the local "Tempio Crematorio." His funeral, which took place on the 3rd inst., was one of the most largely attended and the most impressive lately witnessed in Florence. The leading lights of the Florentine and other Tuscan schools, whether in the medical, legal, or literary faculties, were numerously represented, and professional colleagues from all parts of Italy, and even foreign delegates like Professor Moriz Schiff of Geneva, assisted in person. Notable in the funeral *cortège* was the large attendance of students of present and former years, and still more so the few survivors of the revolution of 1848, who, under the banner of the "Reduci delle Battaglie Patrie," accompanied their old companion-in-arms to his last resting-place. A selection from his numerous papers and prelections on obscure points of syphilitic and cutaneous diseases will, it is understood, be collected shortly and, preceded by a biographical memoir, be published. Dr. Pellizzari was in his seventieth year.

### DR. JULIUS VON BEREKSZASZI.

To students who have worked at laryngology or rhinology in Vienna the name of Dr. Julius von Berekszaszi is familiar. Those who were so fortunate as to be admitted to his classes regarded him with respect and affection. All who knew him will be grieved and surprised to hear that he died recently of aneurysm of the aorta. He was only forty-five years of age, and from his appearance seemed destined to live the full span allotted to mortals. His death took place during a holiday visit to Bad Zardpoort in Holland. Shortly after his bath he sank down before the door of his hotel and expired. Dr. Berekszaszi will be greatly missed by a large circle of

friends. By his genial manner he had endeared himself to his colleagues as well as to students and patients. More than one thousand letters of condolence were received by his widow.

## Medical News.

**EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.**—The following gentlemen passed the Second Examination of the Board in Anatomy and Physiology at a meeting of the Examiners on the 10th inst. :—

Julio D. Amenábar, of Owens College, Manchester; Edward L. Roberts and Horace R. Wilson, of University College, Liverpool; James Boyd, of Glasgow University and St. Mary's College; William J. Gray, of Edinburgh University; Edward T. Coady, of the Catholic University, Dublin; John A. Hall and Leonard K. Thomas, of Mason's College, Birmingham; Stephen Y. Howell, of the College of Physicians and Surgeons, New York.

**Anatomy only**—Harold Jackson, of Yorkshire College, Leeds, and St. Mary's Hospital; Sydney Crompton, William S. Freer, and William Sutcliffe, of Mason's College, Birmingham; John B. Chadwick, Harry P. Dalley, and William Chapman, of Owens College, Manchester; George R. Sparrow, of University College, Liverpool; John A. MacPhail, of McGill College, Montreal; Edward J. C. Kennedy, of McGill College, Montreal, and Mr. Cooke's School of Anatomy and Physiology.

**Physiology only**—Cyril H. Flory and Herbert A. L. Banam, of Sheffield Medical School; Percy A. Chilcott, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; Duncan N. MacLennan, of Queen's College, Kingston, Canada, and London Hospital; Arnold J. Thompson, of Mason's College, Birmingham; Charles A. Phillips, Percy Kitchen and William S. Dibbs, of Yorkshire College, Leeds; John H. Wigham, of Yorkshire College, Leeds, and St. Mary's Hospital; Albert Hodge, of Owens College, Manchester.

Eleven candidates were referred in both subjects, six in Anatomy only, and six in Physiology only.

Passed on the 11th inst. :—

**Anatomy and Physiology**—Charles E. Layton and George C. Belcher, of Mason's College, Birmingham; Charles G. Higginson, of Owens College, Manchester; Eldon Pratt, of St. Bartholomew's Hospital; Robert A. Nesham and James R. Kingdon, of Cambridge University and St. Bartholomew's Hospital; Chintaman R. Bakhtia, of Grant Medical College, Bombay; Robert P. Smallwood, of Cambridge University; George W. Penny, of St. Thomas's Hospital.

**Anatomy only**—Arthur Cant, of Mason's College, Birmingham; Mohamed A. Ghani, of Lahore Medical College, Punjab; Frank R. Proctor-Sims and Richard L. Roberts, of Guy's Hospital; Guy P. U. Prior and John R. Benson, of King's College; Finch White, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; Frederick E. H. Keogh, of St. Mary's Hospital; John S. Hosford, Gerald H. Goddard, and John Blackwood, of University College; Alfred B. Wright, of London Hospital; Alfred W. Wilson, of Melbourne University and London Hospital; Alexander S. Grant, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; Walter P. X. Hopkins, of St. Bartholomew's Hospital.

**Physiology only**—Edward H. Phillips and George Y. Myrtle, of Yorkshire College, Leeds; Arthur T. Jones and Henry W. Lloyd, of University College, Liverpool; William E. Bracey, of Mason's College, Birmingham; Ernest William Ormerod, of Bristol Medical School and Mr. Cooke's School of Anatomy and Physiology; Joseph Broadbent and John T. Barritt, of Owens College, Manchester; William M. Coghlan, of St. Bartholomew's Hospital; Walter H. Morgan, of Charing-cross Hospital and Mr. Cooke's School of Anatomy and Physiology; Thomas W. Turner, of London Hospital and Mr. Cooke's School of Anatomy and Physiology.

Eight candidates were referred in both subjects, four in Anatomy only, and eleven in Physiology only.

Passed on the 12th inst. :—

**Anatomy and Physiology**—Harry J. M. Smith and John W. Bird, of Guy's Hospital; Herbert S. Oliver, of Charing-cross Hospital; Herbert E. Gibson, of University College; Robert Hughes, of St. Thomas's Hospital; Charles H. Hopkins, of St. Bartholomew's Hospital; George C. Hancock, of Westminster Hospital and Mr. Cooke's School of Anatomy and Physiology.

**Anatomy only**—William G. Mitchell, Berthon F. Pendred, Ellis R. Thomas and Archibald A. Price, of Guy's Hospital; Edgar Thomas Inkson, of University College; Ernest T. Clayton, of Charing-cross Hospital; Richard Armitage, of St. Bartholomew's Hospital.

**Physiology only**—Edgar T. Lanyon and Alfred E. Sears, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; Eugene Moore, of Guy's Hospital; Alfred W. Hayles, of King's College; Edward G. Moon and Basil Pares, of St. Mary's Hospital.

Fifteen candidates were referred in both subjects, three in Anatomy only and nine in Physiology only.

Passed on the 13th inst. :—

**Physiology only**—John W. Ensor and Ernest H. Tipper, of Guy's Hospital; Lionel H. Y. Stephens, of Yorkshire College, Leeds, and Guy's Hospital; Cyrus W. Smith, Joseph L. F. de Gannes, Algernon C. Bean and Arthur B. E. Sworn, of University College; Samuel B. Blomfield, of Westminster Hospital and Mr. Cooke's School of Anatomy and Physiology; James H. de Villiers, George W. Brown, Frank E. Saunders and Percy L. Blaber, of St. Thomas's Hospital; George Candler, of Cambridge University and St. Thomas's Hospital; Thomas Horbert, Francis H. Bailey-King and Alan P. Brehm, of Middlesex Hospital; Alfred K. M. Curtis and Lewis Savin, of Middlesex Hospital and Mr. Cooke's School of

Anatomy and Physiology; William T. Dempster, Thomas H. Parker and Alexander S. McSerey, of King's College; William F. Brooks, of Charing-cross Hospital; Hubert H. Thomas, of Charing-cross Hospital and Mr. Cooke's School of Anatomy and Physiology; Thomas Hood and Arthur H. Beadles, of St. Bartholomew's Hospital.

Eleven candidates were referred in Physiology.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.**—The following have passed the Second Professional Examination:—

U. J. Burke, T. Cairns, R. Coffey, E. P. Coogan, B. Coyle, C. J. Fallon, L. A. Hare, R. Hassard, E. J. Hogan, T. J. Jordan, H. T. Kennedy, W. P. Marriott, J. G. Morgan, I. J. M'Donogh, C. J. O'Gorman, H. S. Roberts, W. Ryan, J. Sheridan, S. Stewart, W. Stratton, J. H. Walsh, J. S. Watson and M. A. Wilmé.

**ROYAL UNIVERSITY OF IRELAND.**—The following have passed the Medical Degrees Examination:—

*Upper Pass Division*—James Lyness, William A. Rountree. (These candidates may present themselves for the further examination for Honours.)

*Pass Division*—James F. Barrett, Francis Brannan, Francis H. Clements, Peter Deo, Hugh J. Dickey, Victor G. Fielden, Matthew Ledwich, Herbert C. Mooney, Adam Moss, Patrick J. O'Brien, Daniel O'Callaghan, John O'Donnell, Daniel O'Driscoll, Thomas Pedlow, Joseph M. Richey, Lawrence Rowan, David J. Ryan, Howard Sands, James A. Scott, John Scott, William Scott, Edwin S. Topping, Edward T. Vint and John J. Yorke.

*Diploma in Mental Diseases*—John Mills and William C. Sullivan.

The following have passed the first examination in medicine of the University:—

Hugh Bell, H. F. Browne, Wm. Calwell, S. D. Clements, W. G. Cousins, S. L. Cummins, J. Danaher, J. Dorgan, F. E. Dowling, D. Fleck, T. H. Gloster, E. S. Gorman, T. F. Heas, J. T. Hunter, R. J. Johnstone, T. Kennedy, E. A. Kirkwood, J. Kirwan, E. J. Liddle, Geo. Liddle, J. M. Lynch, J. H. McComb, P. W. McHugh, F. C. McKee, T. Magner, Wm. McWhirter, A. Montgomery, D. H. O'Brien, T. P. O'Carroll, R. O'Flaherty, E. F. O'Sullivan, J. Park, J. Shinkwin, J. Slattery, R. B. Throfall, W. White, and William J. Wilson.

The undernamed will be allowed to present themselves for honours in the following subjects:—

*Botany*.—W. J. Cousins, R. J. Johnstone, E. J. Liddle, W. H. Mewhlrter, E. F. O'Sullivan, James Park, Wm. White, Wm. J. Wilson

*Zoology*.—J. Dorgan, E. S. Gorman, R. J. Johnstone, Thos. Kennedy, E. J. Liddle, J. M. Lynch, T. O'Carroll, J. B. Slattery, William White.

*Experimental Physics*.—S. D. Clements, T. H. Gloster, E. S. Gorman, Robert J. Johnstone, Thos. Kennedy, James St. L. Kirwan, Alexander Montgomery, Daniel H. O'Brien, Joseph Shinkwin, William White.

*Chemistry*.—E. S. Gorman, Robert J. Johnstone, Thomas Kennedy, Daniel H. O'Brien, Patrick E. O'Flaherty, and William White.

**MEDICAL MAGISTRATE.**—Dr. T. Starkey Smith, of Warrington, has been placed on the Commission of the Peace for that borough.

**METROPOLITAN ASYLUMS BOARD.**—The number of patients remaining in the several fever hospitals of the Metropolitan Asylums Board at midnight on Oct. 18th was as follows:—Eastern Hospital, 404 scarlet fever, 53 diphtheria and 45 enteric fever; North-Eastern Hospital, 218 scarlet fever; North-Western Hospital, 401 scarlet fever, 101 diphtheria and 17 enteric fever; Western Hospital, 304 scarlet fever, 39 diphtheria, 1 typhus fever and 18 enteric fever; South-Western Hospital, 304 scarlet fever, 55 diphtheria and 25 enteric fever; South-Eastern Hospital, 395 scarlet fever, 26 diphtheria and 13 enteric fever; Northern Hospital, 904 scarlet fever and 17 diphtheria; Gore Farm Hospital, 779 scarlet fever. On the hospital ship *Atlas* there were 5 cases of small-pox.

**CHARITABLE BEQUESTS.**—It is not often that great wealth accumulated by commercial enterprise comes to be so beneficently bestowed as in the case of the distribution of the effects of the late Mr. Berridge. The trustees, too, are to be congratulated on the judgment with which they have, according to our information, apportioned the legacy of £150,000 recently bequeathed by the testator for public purposes chiefly connected with public health. The Sanitary Institute receives £10,000; the British Institute of Preventive Medicine £40,000; King's College, £10,000 towards the expenses of founding its Public Health Department; University College £10,000, for the chair of Hygiene. The sum of £2000 is to be handed over to the Plumbers' Company in support of their scheme for the registration and training of plumbers; whilst a large sum has been set apart for the teaching of cookery in schools. The late Mrs. Maria Macdonald of Newcastle has bequeathed the following charitable legacies:—Newcastle Infirmary, £1000; Blind Asylum, £300; Sick Children's Hospital, £300; Northern Counties Orphanage, £300; Boys' Refuge, £300; Aged Female Society, £300.

**THE NORTH BIERLEY JOINT HOSPITAL.**—This new hospital for infectious diseases, erected by the North Bierley Joint Hospital Board, was formally opened on Saturday by Mr. Arthur Anderson of Cleckheaton. The total estimated cost of the site, buildings and furnishing is £8500. The buildings comprise an administrative block, a pavilion with two wards of six beds each, an isolation block, with four wards and ten beds, a mortuary and other necessary accommodation.

**MEDICO-PSYCHOLOGICAL ASSOCIATION.**—There will be a meeting of this Association at Mullingar Asylum on Oct. 27th, when the following papers will be read:—Dr. Finnegan: Dress of Asylum Inmates. Dr. West: Farms for Asylums. Drs. J. N. Eustace and Parsons: Pachymeningitis Hæmorrhagica Interna. Dr. Nash: (a) Alcoholic Neuritis and Insanity; (b) Puerperal Insanity with High Fever. Dr. Rutledge: Muscular Atrophy limited to certain groups of muscles. Dr. Nolan: Syphilitic General Paralysis.

**UNIVERSITY OF ABERDEEN: EXAMINERS FOR GRADUATION IN MEDICINE.**—The University Court, at a meeting on Oct. 11th, appointed the following to be examiners for 1892-3:—Anatomy: Bertram C. A. Windle, M.D. &c., Mason College, Birmingham. Botany and Materia Medica: Jas. Galloway, M.D. Lond. Chemistry and Medical Jurisprudence: Alfred Hill, M.D. Aberdeen, Birmingham. Natural History and Institutes of Medicine: George N. Stewart, M.D. Camb. Practice of Medicine and Pathology: Sidney Coupland, M.D. Lond. Surgery and Midwifery: George M. Edmond, M.D. Aberdeen.

**ROYAL COLLEGE OF PHYSICIANS IN IRELAND.**—The following officers have been elected for the ensuing year:—President: W. G. Smith. Vice-President: J. Moore. Censors: J. Moore, C. Norman, Joseph O'Carroll, W. Smyly. Additional Examiners to take the place of an absent Censor: Medicine, H. C. Tweedy; Medical Jurisprudence and Hygiene, Joseph Redmond; Midwifery, A. Horne. Examiners for the Licence to practise Midwifery: A. J. Horne, A. V. Macan. R.C.P.I. Examiners under the Conjoint Scheme with the R.C.S.I. (not including the above Censors, who examine at the Fourth Professional Examination)—Chemistry and Physics: H. T. Bewley, Edwin Lapper. Materia Medica and Pharmacy: Ninian Falkiner, F. J. Quinlan. Physiology: John Purser. Medicine (second and third professional examinations): W. Beatty, E. Cosgrave. Hygiene and Forensic Medicine: John Molony. Membership Examiners—Clinical Medicine: J. Moore, Joseph O'Carroll. Pathology: H. T. Bewley, C. Norman. Practice of Medicine and Principles of Public Health: Joseph Redmond, H. C. Tweedy. R.C.P.I. Examiners for the Conjoint Diploma in State Medicine—State Medicine and Hygiene: F. J. Quinlan. Meteorology: J. Moore. Chemistry: Edwin Lapper. Engineering: A. Murray. R.C.P.I. Examiners in Preliminary Education—Science: E. Cosgrave. Languages: H. T. Bewley. R.C.P.I. Representatives of the Committee of Management: J. M. Finny, T. Grimshaw, C. J. Nixon. Representative on the General Medical Council: L. Athill. Registrar: G. Nugent. Librarian: S. Wilson.

**FOOTBALL CASUALTIES.**—On the 6th inst., while teams representing the Victoria Rangers of Aberdeen and the Cutter Club were playing a match at Cutter, a member of the latter club, aged twenty-three, came into collision with another player and received injuries from which he died the next day.—During a match (Brimington United against Brimington) on the 11th inst. a player had his "kneecap severely kicked."—The following four accidents occurred on Saturday: In a match at Holburn (Thistle against Grammar School, F. P.), the Thistle Club captain sustained a serious injury to the nose; during a match (Branston Unity against Perriams Teams) at Sattley a player, aged twenty-one, collided with another player and fractured his left leg; in the course of a match at Kelbourn-park, Kelvinside, Glasgow (between the Perthshire Athletic Club and the Royal Scots Fusiliers), a member, aged twenty-five, of the Perthshire team had his left leg fractured above the knee; also a boy aged eleven, while playing in a field off Dumbrick-road, fractured his leg.—In a match between some youths in the Vicarage-road, King's Heath, a player, in attempting what is called a "scrow kick," gave himself a violent twist, death ensuing shortly afterwards. A post-mortem examination revealed that the intestines were twisted and caused the fatality.—A boy aged seven, while playing in a game on Tuesday in Gledhow-street, Leeds, received an injury to his leg and was admitted to the Leeds Infirmary.

**MEDICAL CORONER.**—Mr. Albert Green, M.B. Lond., M.R.C.S.; L.R.C.P., has been appointed deputy coroner for the Hundred of Scarsdale, North Derbyshire.

**SCARLET FEVER AT SOUTHAMPTON.**—An outbreak of scarlet fever has taken place at Southampton, resulting in the closing of a school. So far it has been strictly localised, and all the cases have been conveyed to hospital. One person has been fined 5s. for illegally exposing his son in the street whilst suffering from the disease.

**CHESTER INFIRMARY.**—The new Humberstone wing of this infirmary was opened by the Duke of Westminster on Wednesday last. The addition has cost upwards of £2500, and was designed as a memorial of the late Colonel Humberstone, who for twenty-five years acted as chairman of the board of management of the institute.

**ST. VINCENT'S HOSPITAL, DUBLIN.**—The following prizes have been awarded for the past session:—Senior Class—Bellingham Medal in Clinical Medicine: James P. Marnell. O'Ferrall Medal in Clinical Surgery: James F. Barrett. Third Year's Class—Prize: John R. O'Brien. Junior Class—Junior Clinical Prizes: John H. Davis and Patrick F. Morrissey (equal).

**ANOTHER UNDERGROUND LAVATORY.**—In opening to the public the underground lavatory in Watterton-road on Thursday, the 13th inst., Mr. John Williams, chairman of the Works Committee, stated that the vestry had now been convinced that establishments of this kind, if carefully managed, were self-supporting, and expressed a hope, endorsed by Mr. Whur, Deputy-Surgeon-General Jessop and Mr. Rayner, that the time was approaching when lavatory accommodation would be provided in all suitable thoroughfares in the parish.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—Sir James Paget, President, took the chair at the quarterly Court of Directors held on Wednesday, Oct. 12th. Fifty-eight widows, 12 orphans and 4 orphans on the Copeland Fund made applications for grants and it was resolved that a sum of £1256 should be distributed among them at the next Court. The directors had great pleasure in recommending that a Christmas present should be given this year to the widows and orphans on the fund—viz., £5 to each widow, £2 to each orphan and £5 each to the 4 orphans on the Copeland Fund—in all, £334. Four new members were elected and the deaths of 4 reported. The death of a widow was announced and 3 orphans had ceased to be eligible for further grants. The expenses of the quarter were £63 14s. 6d. A legacy of £20 had been received from the executors of Mr. J. G. Davies, a life member.

**ÆSCULAPIUS LODGE, No. 2410.**—The installation meeting of this lodge was held on Wednesday, the 12th inst., at the Café Royal, Regent-street, W. Brother Brindley James, P.M., W.M., presided, and there were also present, besides the officers of the lodge, Brothers the Rev. R. J. Simpson, M.A., P.M., P.G. Chap.; Ralph Gooding, M.D., P.M., P.G.D.; M. Coates, M.D., P.M.; W. Ernest Dring, P.M.; Lewis Lewis, H. G. Blackmore, Edward S. Bell, C. Luxmore Drew, M.B., and N. E. Yorke Davies. After the lodge had been opened &c., Brother Brindley James, P.M., installed Brother Deputy-Inspector-General Belgrave Ninnis, M.D., P.M., G. St. Br. as W.M. for the ensuing year. The newly installed Master then appointed the following brethren officers for the year:—Brothers Brindley James, I.P.M., F. Ernest Pocock, M.D., P.M., S.W.; Jacob Pickett, M.D., J.W.; G. Danford Thomas, M.D., Treasurer; Thomas Dutton, M.D., P.M., Secretary; G. Crawford Thomson, M.B., S.D.; Anthony Nutt, J.D.; Lennox Browne, F.R.C.S. Ed., P.M., D.C.; Frank Oldfield, P.M., S.G.; E. H. Ezard, M.D., Steward; Henry W. Kiallmark, P.M., Steward; Samuel Ellis, Tyler; Mr. William Arbuthnot Lane, M.S. Lond., F.R.C.S. Eng., and Mr. Frank Fowler, L.R.C.P. Lond., M.R.C.S. Eng., were then admitted into Freemasonry. Brother J. H. Garland Wrighton, L.D.S. Eng., P.M., was duly elected a joining member. A handsome Past-Master's jewel was presented to Brother Brindley James for the admirable manner in which he had carried on the work of the lodge during the past year. The auditors' report was read by the treasurer and unanimously adopted and other routine business transacted, after which the lodge was closed. The usual loyal and masonic toasts were given at the banquet with commendable brevity, and a very pleasant reunion of the brethren took place.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

**ALLAN, FRANCIS J., M.D., D.P.H.**, has been appointed Lecturer on Sanitary Science to King's College, London.  
**DAUNT, E., L.R.C.P. Lond., M.R.C.S.**, has been appointed Medical Officer for the West Brigg Sanitary District of the Lincoln Union.  
**FOOT, E. G., M.R.C.S.**, has been appointed Medical Officer for the First Sanitary District of the Takeham Union.  
**GOODMAN, F. G., M.D., M.Ch. Dub.**, has been appointed Medical Officer for the East Brigg Sanitary District, Public Vaccinator for the Barnetby Sanitary District, and Medical Officer for the Workhouse of the Lincoln Union.  
**MASON, GEORGE A., M.A., M.B., B.C. Cantab.**, has been appointed House Physician to the Great Northern Central Hospital.  
**MAYNARD, D. F., M.B., C.M. Edin.**, has been appointed House Surgeon to the Sussex County Hospital, vice Calvert, resigned.  
**MERCER, W. B., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P.**, has been appointed House Physician to the Royal Hospital for Diseases of the Chest, City-road, E.C.  
**PEARSE, FRANCIS J., M.R.C.S.**, has been appointed Divisional Surgeon to the A Division of the Metropolitan Police; also Medical Officer to the United Westminster Almshouses.  
**RADFORD, WILLIAM J., L.R.C.P. Lond., M.R.C.S.**, has been appointed Senior House Surgeon to the Poplar Hospital for Accidents, vice Hawtrey Collins, resigned.  
**ROE, M. W., M.R.C.S.**, has been appointed Medical Officer for the Constantine Sanitary District of the Falmouth Union.  
**ROGERS, J. F., L.R.C.P. Edin., M.R.C.S.**, has been appointed Public Vaccinator to St. Luke's Holborn Union, vice Yarrow.  
**SNADDEN, JAMES, M.B., C.M. Edin.**, has been reappointed Medical Officer of Health for the Fourth Sanitary District of the Wortley Union.  
**SMITH, JOHN A., M.R.C.S.**, has been appointed Medical Officer for the Shitlington Sanitary District of the Wakefield Union.  
**SWALLOW, F. McDONALD, L.R.C.P., L.R.C.S. Edin.**, has been appointed Medical Officer of Health for the Rural Sanitary District of the Penistone Union.  
**WEBSTER, A., L.R.C.P. Lond., M.R.C.S.**, has been appointed Medical Officer for the First Sanitary District of the Middlesbrough Union.  
**WILLOCKS, A. D., M.R.C.S.**, has been appointed Medical Officer of the Taunton Workhouse, vice Iles, resigned.  
**WOOD, J. C., L.R.C.P., L.R.C.S. Edin.**, has been appointed Medical Officer of Health for the Sunderland Urban Sanitary District of the Sunderland Union, vice A. E. Harris, resigned.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement.*

**BIRMINGHAM GENERAL DISPENSARY.**—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights and attendance.  
**BRISTOL EYE HOSPITAL.**—House Surgeon. Salary £120, without board or residence.  
**CHURCH OF SCOTLAND JEWISH MISSION.**—Medical Missionary for the mission and Hospital at Smyrna. Salary £300, with dwelling-house. (Applications to the Rev. Dr. Alison, 1, South Lauder-road, or Mr. J. A. Trail, W.S., 17, Duke-street, Edinburgh.)  
**DEVON COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer. Salary £100, rising by an annual increase of £10 to £120, with board, lodgings and washing.  
**EAST LONDON HOSPITAL FOR CHILDREN,** Glamis-road, Shadwell, E.—House Physician. Board and lodging provided.  
**GENERAL HOSPITAL, Barbadoes, West Indies.**—Junior House Surgeon for three years. Salary £200 per annum and quarters. (Applications to the Secretary, General Hospital, Barbadoes.)  
**GLAMORGAN COUNTY COUNCIL.**—County Medical Officer. Salary £750 per annum, of which £150 is intended to cover all travelling and office and laboratory expenses.  
**HENLEY UNION.**—Medical Officer for the Watlington District of the Union. Salary £105 per annum, and the extra remuneration provided by the Order of the Poor Law Commissioners, and 10s. per case for midwifery cases.  
**HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNAECOLOGY),** Soho-square, W.—Clinical Assistants.  
**HUNDERSFIELD INFIRMARY.**—Honorary Physician.  
**LONDON THROAT HOSPITAL, 204, Great Portland-street, London.**—House Surgeon for six months. Honorarium at the rate of £50 per annum.  
**METROPOLITAN HOSPITAL, Kingsland-road, N.E.**—Surgeon.  
**NATIONAL DENTAL HOSPITAL, Great Portland-street, London.**—Anesthetist.  
**NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS,** Soho-square.—Physician.  
**NORTH-WEST LONDON HOSPITAL, Kentish Town-road.**—Resident Medical Officer for six months, and Assistant Resident Medical Officer for six months. Salary for the senior post £50.  
**NORTH-WEST LONDON HOSPITAL, Kentish-town-road.**—Assistant Surgeon.  
**POPULAR HOSPITAL FOR ACCIDENTS, Blackwall, E.**—Junior House Surgeon. Salary £50 a year, with board &c.  
**ROTTERHAM HOSPITAL AND DISPENSARY.**—Assistant House Surgeon for six months. Rooms, commons (exclusive of alcoholic drinks) and washing provided.

**ROYAL NATIONAL HOSPITAL FOR CONSUMPTION**, Ventnor, Isle of Wight.—Assistant Resident Medical Officer. Salary £70 per annum, with board and lodging in the hospital. (Applications to the Board of Management, 34, Craven-street, Charing-cross, London.)

**SHEFFIELD SCHOOL OF MEDICINE**.—Tutor, to take charge of Dissecting Room and hold classes in Anatomy and Physiology. Salary commencing at £100.

**WESTON-SUPER-MARE HOSPITAL AND DISPENSARY**.—Medical Officer to the Provident Dispensary attached to the Hospital. Salary £60 per annum, with board, lodging and washing.

## Births, Marriages and Deaths.

### BIRTHS.

**BAKER**.—On Oct. 15th, at The Hawthorns, Church-end, Finchley, the wife of James Barrington Baker, M.D., of a son.

**BRODIE**.—On Oct. 17th, at Fakenham, Norfolk, the wife of F. Cardon Brodie, M.B., of a daughter.

**HARDING**.—On Oct. 10th, at Douro-place, Dover, the wife of Surgeon-Major A. Harding, Army Medical Staff, of a son (premature).

**HEWITSON**.—On Oct. 16th, at Park Villa, Hetton-le-Hole, co. Durham, the wife of William Andrew Hewitson, M.R.C.S. Eng., L.R.C.P. Ed., of a son.

**HUMPHRY**.—On Oct. 17th, at Townsville, Queensland, the wife of Ernest Humphry, M.R.C.S. Eng., of a daughter.

**POCOCK**.—On Oct. 12th, at Manor-view, High-road, Streatham, the wife of Alfred Pockock, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

**RANSOME**.—On Oct. 13th, at The Downs, Altrincham, the wife of Herbert F. Ransome, L.R.C.P., M.R.C.S., of a daughter.

**SEATON**.—On Oct. 14th, at the Limes, Capham-common, S.W., the wife of Edward Seaton, M.D., F.R.C.P., of a daughter.

**SKIPPER**.—On Oct. 17th, at Tollington-park, N., the wife of Edward Skipper, M.D., of a son.

### MARRIAGES.

**CRAN—BERTRAM**.—On Oct. 12th, at Post Cliffe, Peterhead, Aberdeenshire, by the Rev. James Aird, M.A., Minister of the parish, assisted by the Rev. Gavin E. Argo, M.A., Kincardine, O'Neil Robert Cran, M.D., M.C., Ballater, to Elizabeth Bertram, only daughter of John Johnston.

**FERGUSON—MACHIN**.—On Oct. 18th, at Christ Church, Brondesbury, N.W., by the Rev. C. Dale William, M.A., Rector, assisted by the Rev. W. G. Whinfield, B.A., of the Parish Church, Eastbourne, Robert Bruce Ferguson, M.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., of 26, Woodland-road, New Southgate, N., eldest son of the late William Ferguson, Esq., of Leeds, to Florence, youngest daughter of Frederick Machin, Esq., of Ismeer, Willesden, N.W.

**HAWORTH—KNIGHT**.—On Oct. 12th, at St. John's Church, Cayton, near Scarborough, by the Rev. A. N. Cooper, Vicar of Filey, assisted by the Rev. F. G. Stapleton, Vicar of the Parish, J. T. Haworth, L.R.C.P., L.R.C.S. Edin., of Filey, to Beatrice Mary, youngest daughter of the late J. C. Knight, Chapel Allerton, near Leeds.

**HUGHES—RANKIN**.—At Stambridge Church, Essex, by the Rev. E. F. Russell, of St. Alban's, Holborn, assisted by the Rev. G. W. Keighley, M.A., Rector of the parish, Wilfrid Kent Hughes, M.B. Lond., M.R.C.S., youngest son of the late C. W. Hughes, of Melbourne, to Clementina Jane, second daughter of Alfred M. Rankin, Bromhills, Rochford, Essex. Australian papers please copy.

**TILLEY—TILLEY**.—On Aug. 22nd, at St. Paul's, Rockhampton, Queensland, by the Rev. C. Warrington, Wm. Jas. Tilley, L.R.C.P. Lond., M.R.C.S. Eng., eldest son of William Tilley, late of Krongrat, S.A., to Harriette, widow of the late Thos. Tilley of Gillon, S.A., and third daughter of the late John Law, of Kidderminster, England.

**TUCKETT—SOPER**.—On Oct. 12th, at Wanstead Church, by the Rev. R. D. Swallow, Head Master of Chigwell School, assisted by the Rev. G. B. Doughty and the Rev. L. S. Staley, Walter Reginald Tuckett, M.R.C.S. &c., of Woodford, late House Surgeon of Maldstone Hospital, son of Wm. F. Tuckett, Esq., J.P. Bath, to Annie Jane Philpott (Nancy), eldest daughter of the late Henry Lewis Soper, Esq., of Wanstead. No cards.

### DEATHS.

**BRAKE**.—On Oct. 9th, at Grove-cottage, Porchester, Hants, William Newman Brake, R.N., Deputy Inspector-General of Hospitals and Fleets, aged 70.

**CANNON**.—On Oct. 12th, at 10, Eaton-place, Henry Mills Cannon, Surgeon-General, aged 72.

**CARLAW**.—On Oct. 10th, at the Crescent, Sandgate, John Carlaw, M.D., Surgeon-Major, late of H.M. Forces, aged 61.

**EVANS**.—On Oct. 18th, at The Hyde, Middlesex, Conway Evans, M.D. Lond., aged 62.

**FASSON**.—On Oct. 15th, at Meadow-walk, Edinburgh, Charles Hamilton Fasson, Deputy Surgeon-General, Superintendent of the Royal Infirmary of Edinburgh, aged 72.

**HAWKINS**.—On Oct. 17th, at Wellington-place, Cheltenham, Clement James Hawkins, F.R.C.S., aged 78.

**MAC KENZIE**.—On Oct. 16th, at 47B, Welbeck-street, Mr. John Ingleby Mac Kenzie, M.B., Cantab., aged 68.

**MURRAY**.—Suddenly, at his residence, Weymouth-street, Portland-place, James Murray, M.D., aged 63.

**OSWALD**.—On Oct. 15th, at Glencraig, Edinburgh, Henry Robert Oswald, M.D., Surgeon-General H.M. Indian Medical Service (retired), aged 65.

**SPURRELL**.—On Oct. 13th, at Belvedere, Kent, Flaxman Spurrell, M.D., aged 77.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages and Deaths.*

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligenoe of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### ADVERTISEMENT OF CHANGE OF ADDRESS.

**W. J. B.**—Advertisement through a newspaper is objectionable. The proper course is to send a visiting card by hand or post to the patients of the particular practitioner specifying change of address.

**Vizen.**—There can be no doubt that our correspondent is in honour prohibited from practising in a place where he has been the locum tenens of three or four medical men.

**Mr. J. Lister Wright.**—We are obliged for our correspondent's courteous communication. The matter to which he alludes has received attention.

**Mr. John A. Bright's** communication has reached us too late for publication in our present issue

**T. B. G.** has not enclosed his card.

### "EXPERIENTIA DOCET."

To the Editors of THE LANCET.

**Sirs,**—Kindly allow me, by relating a late experience, to caution country practitioners how they give orders to travellers from firms in distant towns.

On Feb. 1st, 1889, a traveller from a firm called — and Co. called and importuned me so that I gave him an order for about £2 worth of small instruments &c. The order was badly executed: some articles not sent, and one I returned, being only half the size of the one ordered. For what I kept I at once sent a cheque, which was cashed, but never yet acknowledged in any way. Eight days later, on returning from my morning round, I found a parcel that had arrived by railway and the fare on which my servant had unfortunately paid in my absence. I opened the parcel, and to my surprise found an expensive article I had distinctly told Messrs. — and Co.'s traveller not to send. It was at once returned, and a letter sent stating that it had

never been ordered and must have been sent by a mistake. Messrs. — and Co. refused to take it back, and threatened me with legal proceedings if I did not pay for it. As I had then a witness (who died in January this year) who heard me tell the traveller not to send the article, I replied they could do as they pleased. From that date (Feb. 25th, 1880) to July this present year (nearly three years and a half) I heard nothing from them, and then was served with a county-court summons for the article, priced higher than its published price. This week I defended in —, and the judge ruled that I was liable since the railway fare had been paid by me, although there was nothing to show what was in the parcel, as the plaintiffs neither in their bill or otherwise advised me (as they could and should have done) that it would be forwarded. Judgment was given for nearly 5s. less than claimed.

I wish practitioners to note that in all such cases they must defend in the towns the plaintiffs belong to and not in those where the orders were given, also the danger of receiving and paying for carriage on parcels with unknown contents. If an order is given in the way mine was it would be well to have an exact copy of it signed by the traveller. Perhaps best of all is to give no orders whatsoever to strangers, however they importune, and so escape the trouble, annoyance and expense I have experienced. I am, Sirs, yours truly,  
Ormskirck, Oct. 16th, 1892. HENRY PILKINGTON, M.R.C.S., &c.

#### INFECTION IN SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—As the question of infection in the early stages of scarlet fever has lately been discussed in your columns, and as one positive case is worth a dozen negatives, I think the following record of cases which happened in my individual experience will be interesting to your readers. It seems to me to prove that sometimes, at any rate, scarlet fever is infectious at the very beginning.

A patient was brought into hospital for, if I remember rightly, leucocythæmia, was placed in the end bed of the back ward nearest the door, and quite close to the ward kitchen door. In a few days' time she developed scarlet fever, and was removed to the fever hospital as soon as the rash was pronounced. The ward was not disinfected, but the bedstead &c. was—the bedding being, in fact, destroyed, floor and walls scrubbed with carbolic, and, in short, all the ordinary precautions were taken, in spite of which the next patient placed on the bedstead developed the disease. The same precautions were again gone through, but again the next patient developed scarlet fever. And this went on for quite a series of cases—I believe six or seven,—including the ward maid (who passed the bed frequently on her way to and from the kitchen) and one of the clerks of the ward; but no case occurred in any other bed in the ward. Finally, the whole ward was turned out, all the bedding destroyed and the place thoroughly disinfected with sulphurous acid. After this there were no more cases. There had been no scarlet fever about the hospital previously.

To me this occurrence affords unmistakable evidence that scarlet fever must be in some instances infectious during the first stage. Moreover, the peculiar obstinacy of the infection and the vigorous measures necessary to getting rid of it were well shown.

I am, Sirs, yours truly,

E. D. FITZGERALD, M.R.C.S., L.R.C.P.

Sandgate-road, Folkestone, Oct. 18th, 1892.

#### "GREEK AND THE M.D. DEGREE."

To the Editors of THE LANCET.

SIRS,—Your correspondent's letter in your last issue on the substitution of German or French for Greek before proceeding to the M.D. degree is one of considerable importance, and affects a large number of men who find it impossible in the worry and work of practice to settle down and grind up Greek; whereas German or French come so much lighter on account of the medical literature that is written in these modern languages. Union is strength; and if the authorities of the universities are made aware of the feeling of graduates of some years' standing on this question they will, I hope, accede to their wishes. The difficulties in the way of signing any petition are so great that it would be almost hopeless to attempt it; but I would suggest that all who feel that it is desirable to make this new regulation retrospective should write without undue delay to the Dean of Faculty, asking if it be possible to grant their request.

I am, Sirs, yours obediently,

Ashburn-place, S.W., Oct. 17th, 1892. AUGUSTUS W. ADDINSELL.

#### "OWNERSHIP OF PRESCRIPTIONS."

To the Editors of THE LANCET.

SIRS,—You say (page 921 of your last issue), "It is obvious that a prescription belongs to the person who pays for it—viz., the patient." It is obvious, then, that the F.R.C.P. is a tradesman and sells his prescription, and thus violates the by-law of that Society. The F.R.C.P. is supposed to accept an honorarium for his advice, and because he does not make up the medicine he advises should be used gives the prescription to be taken to an apothecary, the medicine to be used for the length of time prescribed by the F.R.C.P. It is a fraud on the part of the patient either to use the prescription for a longer time himself than first prescribed or to give the same prescription to another person. It is a fraud also on the part of the apothecary to make up the prescription for any longer time than intended by the F.R.C.P. or for any other person.

I am, Sirs, yours truly,

Oct. 17th, 1892.

H. F. S.

#### MEDICAL PRACTICE IN THE UNITED STATES OF AMERICA.

To the Editors of THE LANCET.

SIRS,—The laws regulating practice in the different States vary considerably. In the New England States, Ohio, Wisconsin and Kansas there are no restrictions at all, while in New York and Pennsylvania a pretty stiff examination must be passed prior to registration. An examination is held at intervals at certain fixed centres in New York State—viz., the University of New York, E. 20th Street (Charles Pardu, M.D., Secretary), Buffalo and Syracuse. The fee is twenty-five dollars. Candidates are examined in anatomy, physiology, medicine, pathology, surgery, obstetrics and hygiene, in a similar fashion to Licentiates of corporations over forty years of age who go in for M.D. of Durham or St. Andrews in this country. Professor Melvil C. Dewey, Secretary to the Regents of the State University, Albany, N.Y., will furnish full particulars of dates and subjects and supply a schedule to be filled up on application. The diplomas of successful candidates are endorsed by the Regents of the State University, M.D.'s having a "special form setting forth the fact," and Licentiates another form somewhat differently worded. The diplomas after endorsement must be registered by the County Clerk—in New York City at the City Hall, and in rural districts at the court-house of the county in which it is intended to practise. The fee is a dollar. If it be wished to practise in two or more counties registration in each is necessary at an additional cost of fifty cents. In Pennsylvania candidates must pass a similar examination at either Jefferson Medical College or the University of Pennsylvania, Philadelphia, those being the only universities empowered to grant medical degrees in the State. In Chicago, which is probably the most suitable opening for an Englishman, the diploma is simply produced before the State Board of Health. Chicago is increasing in population more rapidly than any other city in the States. It now stands second. The States present a very wide field, and it would be no easy matter to predict success or failure in a given instance. A good deal of local prejudice exists against foreigners. They prefer the home-made article, even if inferior. The sanitary laws are enforced very strictly at New York, especially the notification of infectious diseases. The profession, as almost everywhere, is overstocked; but it will be said that "there's always room at the top." A polyglot dictionary would not be a bad investment to start with. I am not joking. I have had Greeks, Poles, Russians, Armenians, Hungarians, Chinese, Italians and Dutch patients. Some speak a little English; but the greater part of the conversation was carried on by signs or through interpreters who know little more than the patients themselves. The fees depend on the class of the *clientèle*. Working men pay a dollar per visit, and the same for advice and prescription; small shopkeepers &c. two dollars, and so on upwards. Midwifery from ten to twenty dollars and upwards, according to class. Medical men never do their own dispensing, unless in the backwoods. The chemists in Pennsylvania are well qualified, many being Doctors of Pharmacy. All Government appointments—such as coroner, medical officer of health &c.—are open to citizens only, but a foreigner may, of course, act as surgeon to Oddfellows, Foresters or any private clubs. Practices are rarely bought or sold as in England. Beware of them as an investment. A practitioner usually starts on his own account—"hangs out his sign," as the local phraseology goes, or he may occasionally obtain an assistantcy to an older man. Assistantships are difficult to secure, because local men "know the ropes" better and are accordingly more sought after. A surgeon in the army or navy becomes *ipso facto* a citizen. I fear my communication grows lengthy, so I shall conclude by saying that the prospects of most men with British qualifications would probably be better in a British colony, although I am personally acquainted with four such in New York city (two being hospital surgeons) who have done well; but I am convinced they would have done equally well, if not better, in any English or Australian town presenting sufficient scope.—Yours truly,

J. A. McMUNN, M.D.

(Registered at New York in 1891).

#### LUNACY CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—Four months ago I received a magistrate's order to examine a person as to her mental condition. After several visits to assure myself of her mental unsoundness I certified her. The day after I did so she was so weak from self-starvation that I delayed her removal for six weeks and had her fed with nutrient enemata during that time. Then I re-certified her and she was removed, but, as I afterwards casually heard, only to the union infirmary, not to the asylum. I have not been paid for my certificate. The usual course of late years is for the magistrates' clerk to direct the Poor-law guardians to pay the medical man who certifies. I called upon the magistrates' clerk, but could not get a satisfactory reply from him. On a former occasion I was not paid for certifying the patient because (as I was informed by the partner of the magistrates' clerk) the patient was not sent to the asylum but to the union infirmary. I do not see that the medical man has anything to do with that.

I should feel obliged if you would kindly inform me what steps I ought to take, as I consider it monstrous that after all my trouble I am to be defrauded of my fee. And I should be glad to know whether I should be at liberty to refuse to act upon receiving any future magistrates' orders, or if I am compelled by law to examine and report without fee or reward. In this latter instance I still have the magistrates' order by me; but in the former case I was directed (rather smartly, I thought) to write my report on the back of the magistrates' order and not upon a regular printed form.

Yours truly,

THORAX.

## Harveian Oration.

### HARVEY AND HIS SUCCESSORS.

*Delivered at the Royal College of Physicians of London on  
Wednesday, Oct. 18th, 1892,*

By J. H. BRIDGES, M.B. OXON., F.R.C.P. LOND.,  
MEDICAL INSPECTOR TO THE LOCAL GOVERNMENT BOARD.

MR. PRESIDENT AND GENTLEMEN,—Within a few days of Shakespeare's death, William Harvey, physician to St. Bartholomew's Hospital, opened his course of lectures as Professor of Anatomy and Surgery at this College. The rough notes used by him in these lectures were published a few years ago by the College in facsimile, and few documents of greater importance for the history of European science have been given to the world in the present century. For not merely do we find in it clear proof of the completeness of Harvey's great discovery twelve years before the accepted date of its publication, but it opens a window through which we may watch the workings of a powerful and most original mind, and appreciate the breadth with which at a most critical period of scientific history he handled the problems of life. In appreciating the life of a great man, as in that of the humblest protozoan, we have to bear in mind the essential fact of life first propounded by Comte and subsequently illustrated with such fulness by Herbert Spencer, that it is a mutual action, ever tending to adjustment, between organism and environment. The environment of higher organisms, no longer limited to the contact of surrounding particles, embraces all the social and intellectual influences to which a highly organised brain may be sensitive. Estimated in this sense what was the environment of Harvey? He was born at the greatest period of English history, not that of her world-wide empire, of her enormous wealth, of her crowded population, but the period in which she gave birth to her greatest men. Within the compass of Harvey's life there lived on this island Shakespeare, Spenser and the galaxy of Elizabethan dramatists, followed by the great epic poet, who was in his prime when Harvey died. In philosophy there were Bacon, Hobbes, Locke. In science there were Napier and Briggs, the inventors of logarithms; Hariot, the forerunner of the mathematical revolution of Descartes; Wallis, the algebraical precursor of Newton; Gilbert, the founder of electrical science; and that most fertile and ingenious of physicists, Robert Boyle. If statesmanship were in question, it would be sufficient to name Elizabeth and Cromwell.

Passing from England to the Continent we may say that Harvey was born into the full splendour of this philosophical and scientific Renaissance. In art the Renaissance had set in a century before, under Ariosto, Raphael, Da Vinci and others. The awakening of science was not slow to follow. Thirty years before Harvey's birth the "Revolutions of Celestial Bodies" had been published in the last month of its author's life. The work of Copernicus was carried on during Harvey's youth by Tycho Brahe and Kepler. The cometary genius of Bruno was flashing through the universities of Europe, preaching the gospel of the new astronomy; and with a yet greater man than these the young Harvey was brought into near contact. In 1597 Harvey took his degree at Cambridge, at that time a school of no great importance; in the following year he went to Padua, and studied under one of the greatest among the many great anatomists of that century and country, Fabricius of Acquapendente. Six years before this time a young man had been appointed to the professorship of mathematics in that university who was to open a new epoch in European thought. Galileo Galilei had already made his mark in his native city of Pisa. He had studied medicine under Cesalpino, chafing no doubt under his interminable pedantries. He had made his brilliant discovery of the equality of time in the oscillations of the pendulum, and had applied that discovery, by a pendulum of suitable length, to the study of the speed and regularity of the pulse; the first instrument perhaps ever constructed for the precise observation of phenomena in a living organism. He had already done fierce battle with the

powers of darkness in attacking the petrified philosophy that was called Aristotelian, and in laying the foundation of the true science of motion. The mathematics in which he was interested were applied mathematics; the interpretation and measurement of physical forces. From the beginning to the end of his life his unflinching conviction was that the phenomena of motion and energy which constituted the world were calculable quantities. The very use of the word "mechanics," to denote the abstract sciences of static and dynamic, dates from his treatise, published in 1593, on the Utility of the Scientific Study of Machines. In this work the great modern conception of the conservation of energy is, I believe for the first time, traceable in his discussion of the paradox that the smaller weight on the longer arm of the lever balanced the heavier weight on the shorter one. "Philosophy," he said, "is written in the great book of the universe, which lies always open, but we must first understand the language and the character in which it is written; that language is mathematics. Without it we cannot understand the words, and wander through a dark labyrinth without a clue." His lecture-hall in Padua held 2000 students, and was crowded with strangers from every part of Europe. He had the art of forming a school and of attracting young men round him. Torricelli, the first measurer of atmospheric pressure, was one of his pupils. The thermometer, first invented by Galileo himself in an imperfect form, was completed by another pupil shortly afterwards. Of the telescope I need not speak; and again it must be repeated that Galileo took the first step to that all-important condition of science—the precise measurement of time. In a word, the science of physics was founded by Galileo. Of personal intercourse between Galileo and Harvey we have no record, but that the influence of his mighty genius is to be taken into account as one of the incident forces which moulded his mind there can be no doubt whatever. He came back from Padua with the sense that nature was not merely to be observed, but measured. He had imbibed elementary truths as to motion and energy which stood him in good stead when he began himself to think on the mechanism of the human body.

Let us briefly review the condition of biological science at the close of the sixteenth century. It may be summed up in one sentence—an advanced state of descriptive anatomy; hopeless confusion as to the functions of the organs described. The debt we owe to the descriptive anatomists of the sixteenth century has perhaps never been adequately recognised, though Vesalius, Eustachius, Fallopius and others have left their names inscribed on various structures of the human body. They were the worthy successors of Galen, whose works are themselves a cyclopaedia of the anatomical and medical knowledge gained in the schools of Alexandria, enlarged by his own observations and experiments. In the schools of Padua, Bologna and Pisa every part of the body was dissected and scrutinised as minutely as was possible before the invention of the microscope, and none more minutely than the heart. With regard to the functions of these organs, the confusion of men's minds was complete and seemingly hopeless. Physiological science was far below the level at which Galen had left it. He was a strictly scientific observer and thinker, inheriting the results of six centuries of Greek inquiry, from Hippocrates onwards, and pushing them forward with marvellous zeal. In the thirteenth century the great schoolmen—notably, Albertus Magnus and Roger Bacon—had shown themselves his worthy successors. They brought Aristotle's scientific researches into prominence, and held them up as models for imitation. Afterwards came a time of stagnation and retrogression. For several generations the professorial chairs of Europe were filled by men who worshipped Aristotle not as a keen observer of nature and a progressive thinker, but as an inspired prophet who saved them the trouble of thinking. Even their Greek science they read backwards. If Galen in the second century A.D. differed from Aristotle in the fourth century B.C., so much the worse for Galen. Thus, for instance, we find the man who is sometimes held up to us as the true discoverer of the circulation—Cesalpino of Pisa—rejecting Galen's admirable investigations into the nervous system, and reverting to the curious doctrine of Aristotle, that the brain was a refrigerator of the blood which had been raised to boiling point in the heart. Similarly on respiration, where Galen's views, though very imperfect, were far less wide of the mark than Aristotle's, Cesalpino had no hesitation in following Aristotle rather than Galen. Pedantry, obscurantism, indolence account for much of this, but not for the whole. The doctrines of the Church had become inseparably intertwined

with Aristotelian metaphysic and logic. To assault Aristotle was to proclaim yourself a heretic.

Now, by Aristotle and all his successors the heart was regarded as a furnace, or at least a reservoir of heat, by the agency of which animal heat was maintained and the food was concocted. It was regarded also by Aristotle, though not by Galen, as the *sensorium commune*; it was the first organ that arose in the embryo, it was the last to die; it supplied the tissues with that which made them sensitive. In the fifth of the Peripatetic Discussions of Cesalpino we have the following thesis maintained. The soul is not made up of separate parts, each residing in a separate organ; nor does the whole soul reside in the whole body, but the whole soul resides in the heart. He quotes with approbation the view of Aristotle that the animal is a commonwealth of organs, the soul being the ruler of that commonwealth. The heart is the soul's court; and as in a community all things are done by the soul's decree, though the king does not intervene in each detail, so do all organs live by virtue proceeding into them from the heart. For instance, in the function of respiration, the beginning of the series of actions concerned was the heart's heat. The blood boiling up in the heart not merely dilates the heart and so produces the pulse, but it dilates the lungs also by sending into them a continual stream of heated blood. The lungs being thus enlarged, it follows that external air streams in through the bronchi, and this we call inspiration. Thence results a cooling of the blood and a diminution of its bulk, as when drops of cold water fall on boiling oil. The lungs collapse and air is given out. This we call expiration. The heart's heat is thus the initial force in respiration. The whole of this alchemistic apparatus set up inside man's body, the heart boiling the blood to the point of evaporation, the subtler spirit thus produced condensed in the cooling chamber of the brain and issuing from it in the form of nerves, the lungs acting as an additional cooler, so that the part of the blood which remained liquid might be brought to the right temperature—all this confused and complicated fabric melted away as a morning mist before the touch of positive science applied by Galileo to inorganic matter and by Harvey to living organisms.

Let us not be unjust to Harvey's predecessors. It is quite true, and it should never be forgotten, that certain partial anticipations of his discovery had been made in the sixteenth century. By Servetus and by Colombo the transit of the blood from the right ventricle through the lungs to the left side of the heart had been distinctly put forward as the most probable hypothesis; and it is also true that Cesalpino had shown that, in consequence of the arrangement of the mitral and the aortic valves, the flow of blood was from the left ventricle towards the various organs of the body. I quote his actual words: "There is a motion from the veins into the heart while its heat draws in aliment; and at the same time there is a motion from the heart into the arteries, because, owing to the position of the valves, the blood cannot flow in any other way, for the same motion opens both apertures—that of the vein into the heart, that of the heart into the arteries."

Combining the view of Servetus and Colombo with that of Cesalpino, it might seem that a true and complete conception of the course taken by the blood would be reached; but, as a matter of fact by no physician or anatomist of the sixteenth century were they at any moment so combined. Cesalpino was entirely unaffected by Colombo's hypothesis of the minor circulation, and throughout his work I have not been able to find a single reference to it. The substantial identity of the fluid moving through the vascular system was never grasped by him or by anyone else. There were, men thought, two kinds of blood—one which was perpetually being manufactured in the liver and thence sent to the right side of the heart as fuel or aliment for the heart to work upon; the other was the concocted fluid flowing from the heart to the tissues, part of it having passed to the lungs for cooling purposes, and part filtering through the partition wall dividing the right side of the heart from the left. When we leave the consideration of the motion of the blood and turn to that of the motion of the heart, we find Cesalpino, like all his predecessors, hopelessly in error. In his view the expansion of the heart with blood was the efficient cause of the blood's motion, this being produced, as we have seen, by the boiling up of the blood when exposed to the imaginary heat residing in the heart. He insists emphatically that the contraction of the heart was a mere collapse due to a temporary cessation of the boiling process. In death the collapse, he remarks, is complete; in the mori-

bund it is nearly complete. To attribute any expulsive force to the heart in this condition would therefore be out of the question. Thus the pulse results not from systole, but from diastole. Indeed, the consideration of the pulse is the main subject in this chapter of Cesalpino, the question of the heart and its motions being quite secondary. It may be stated broadly that the conception of a complete circulation of the blood and the conception of the heart as a contractile organ exercising mechanical energy were alike foreign to him. Nothing is more interesting than the vivid, pithy way in which the true view both of the heart and of the blood is expressed in Harvey's MS. notes. "The heart, when contracting, moves like a muscle," he says. "By the impulse of the heart there is a perpetual movement of the blood in a circle." Again, if I may quote the quaint mixture of Latin and English, "Constat per fabricam cordis sanguinem per pulmones in aortam transferri as by two clacks of a water-bellows to raise water." The imaginary furnace that had been set up for so many centuries within the human thorax disappeared, and in its place there was an organ of definite construction, comparable with one of Galileo's machines, exercising a measurable amount of energy. The overwhelming importance of Harvey's researches, the feature that marks them as an epoch in the history of modern science, is the positivity of their method. We pass from metaphysical haze into an atmosphere of reality, utility, certainty and precision. He uses every method of biological research, direct observation and measurement, experiment and, above all, the great Aristotelian method of comparison; an instrument of research created, so to speak, by biology, and one so potent in every branch of scientific investigation that, apart altogether from its application to medicine, the science of biology would deserve all the pains that have been spent upon it. It is to the use of the comparative method that Harvey himself explicitly attributes his success, yet to what an extent he used it could hardly be appreciated till the publication of the notes of his lectures. In these the anatomy of eighty animals examined by himself is referred to.

It has sometimes been said, especially of late years, that experimentation on living animals was the process through which Harvey's discovery was achieved; but this, though it has been used as a potent argument before an uninstructed public, has always appeared to me an exaggerated view. I am not about to enter, even in the most cursory way, into the ethics of the subject. It was not imagined in Harvey's time that any ethical problem was involved in it. So far as I can find, the first to recognise the existence of such a problem and to distinguish himself from his contemporaries by voluntarily accepting a certain measure of parsimony and restraint in experiments on living animals was that great and successful experimenter, deep thinker and humane man, Sir Charles Bell. But the question by what methods the discovery of the circulation was reached is one for the dry light of historical research. Harvey's MS. notes show, even more emphatically than his published work, that direct observation of the pulsating heart in the higher vertebrates taught him but little. "Neque visu neque tactu" are his emphatic words in these notes. "I could not follow the heart's motions by sight or by touch, though I watched them for hours together. Videte quam arduum et difficile discernere. See," he says, pointing at the moment to the experiment he was performing, "see how hard it is to distinguish by sight or touch as to dilatation or contraction, which is systole which diastole." When the animal was moribund and the movement slow, or when he operated on cold-blooded animals with a simpler form of heart, he was more successful. When the discovery had been fully made, and the business of convincing others of its truth began, vivisectional experiments were of use to him. But the principal paths that led to the discovery seems to me to have been—first, the conception of the heart as a machine, exercising definite and measurable force on the fluid which it contained; secondly, that for the first time there was an attempt to measure the amount of blood contained in the heart and voided with each contraction, the result being to show that the rapidity of the current, and consequently the mass of blood returning to the heart, was far greater than could be accounted for by new formation of blood resulting from ingested aliment; thirdly, a far more careful examination of the anatomical facts than had been made by Harvey's predecessors. To the careful study of the heart's valves the important discovery of the valves of the veins, due to Fabricius, was now added and for the first time interpreted. Finally, the whole was illumined by the

light of the comparative method, by the examination of the fetal circulation on the one hand and of the vascular systems of the lower vertebrates on the other. The motto from Aristotle prefixed to his lectures shows that the comparative method was his guiding star. Leaving this part of my subject I pass now to the consideration of the effect produced by Harvey's discovery on the progress of medicine.

It is obvious that Harvey had struck into a new path. His discovery was assuredly the most momentous event in the history of medicine since the time of Galen. It was the foundation stone of scientific medicine. It was the first attempt to show that the processes of the human body followed or accompanied each other in accordance with laws as certain and as definite as those which Kepler was at that time revealing in the solar system, and Galileo in all moving bodies on the earth's surface. Henceforth it became clear that all laws of force and energy that might be seen to prevail in the organic world were applicable to the human body. As an engine performing work the heart stood on the same footing as any of the shipbuilding machines the operation of which Galileo had so carefully studied in the arsenals of Venice. The action of fluids in closed vessels under pressure was investigated in Harvey's youth by Servetus, and in his later life by Pascal. The results were applied at once to the contents of the human vascular system. Still greater prominence was given to Harvey's achievement by the all-embracing philosophy of Descartes, which during the latter part of Harvey's life had secured dominion over the intellect of Europe, and which retained it through the remainder of the seventeenth and a large part of the eighteenth century. That Descartes was among the first to appreciate the importance of Harvey's work has been often mentioned. Yet the question has not so often been asked, Why should Descartes, absorbed as he was in a general philosophy of the universe and of the human mind, have taken special notice of Harvey? It was extremely rare for Descartes to mention the name of any contemporary. I cannot call to mind in his writings more than one or two instances of his doing so. The explanation, as I believe, is this. Descartes had put forward a vast scheme of evolutionary philosophy, in which all the phenomena of the universe were to be explained as resulting from successive differentiations of a primitive homogeneous matter to which motion had been imparted. The scheme embraced the motions of the solar system, the forces of light, heat, gravitation and the phenomena of living beings—all these being conceived as successive differentiations of primitive rectilinear motion impressed on the ubiquitous ethereal substance with which space was filled. In his view there were no facts in nature which were insusceptible of explanation on mechanical principles, and which could not be deduced from such principles by a sufficiently powerful mathematical calculus. He had himself taken the first decisive step towards the construction of such a calculus in his *Geometry* published in 1637, leaving further steps to be taken half a century later by the infinitesimal analysis of Leibnitz, Newton and the Bernoullis. In his treatise on the nature of man Descartes had seized on the facts of the reflex action of the nervous system as illustrations of the automatic mechanical process by which the most complicated phenomena presented to our consideration could be explained. He welcomed Harvey's discovery as a yet more conclusive example of the applications of the new philosophy. The course of the blood, hitherto conceived as governed by vital spirits, by a vegetative soul, or by some other metaphysical fignent of a like kind, was now seen to be determined by natural forces, to be regulated by the same laws of motion as those which governed inanimate matter. We know from the immortal prelude to his *Philosophy*, his *Discourse on Method*, how high were the hopes which Descartes founded on the future of biological research. "Health," he says, "is the first of good things and the foundation of all other good things in this life. For so close is the connexion of the mind with the temperament and the arrangement of bodily organs that if there be any instrument for making the mass of men wiser and more skilful than they have been till now, I believe that medicine is the art wherein to look for it. It is true that the medicine now in use offers little that is strikingly useful. But though I have no purpose to disparage it I feel sure that no one, even of those who now practise it, will deny that what is known is but a mere fraction of what remains to be discovered; and that we might gain freedom from a multitude of diseases both of mind and body, and perhaps also from the enfeeblement of old age, had we sufficient knowledge of their causes and of all the remedies with which nature has provided us."

Thus it was that under the combined influence of Harvey's discovery and of the Cartesian philosophy the vision of scientific medicine, the application of the laws of nature to the art of healing, dawned upon the world in the first half of the seventeenth century. It is worth our while to inquire with what results. Comte has remarked on the fact that the two initial discoveries of physics and of biology, the law of falling bodies and that of the circulation of the blood, were made simultaneously; and he has contrasted the immediate sequel in each case. Galileo's discoveries led by direct roads on one side to Newton and scientific astronomy, on the other to Torricelli, Pascal, Boyle, Mariotte, Black, Watt. To what did Harvey's discovery lead, and why the difference? The truth is that the medicine projected by the ambitious brain of Descartes was from the first foredoomed to failure. It aimed at satisfactory explanation of the facts of living organisms by the laws common to them with other kinds of matter; it recognised no phenomena exhibited by living bodies that could not be so explained. Biology was to Descartes a corollary of physics; it was not an independent department of science, with physics for a foundation, but having a superstructure peculiar to itself, requiring inductions of its own, methods of its own; it was a body of knowledge which was to be made amenable as soon as possible to mathematical treatment. This mode of regarding the subject imported into medicine a spirit of reality, of certainty and of precision which had never before belonged to it; but in each and every case the attempted solution fell short of the mark. There remained always a residuum that could not be accounted for in this way. Hence during the seventeenth and eighteenth centuries two opposing schools of medicine—the first fastening upon the lower more general laws which were susceptible of precise determination; the second dimly recognising the existence of certain higher and more special truths, which, however, they were unable to quantify or even to discern with clearness.

Before describing the opposition of these schools let us take stock of the scientific material available for medicine in the middle of the seventeenth century. We have already seen that in all that related to mechanical force as applied either to solids or fluids the first great steps had been taken by Galileo and Servetus. By Galileo's principal disciple, Torricelli, a discovery had been made the importance of which to medicine cannot be over-estimated—the discovery that the atmosphere had gravity, and that its pressure could be precisely measured. For the first time in the history of medicine the mechanism of the respiratory function became intelligible. It was seen to be a simple result of atmospheric pressure consequent on certain muscular contractions which enlarged the thoracic cavity. To Borelli and to Mayow of Oxford the credit must be given of first describing the respiratory apparatus with unmistakable clearness and accuracy. To Mayow also is due the first, or nearly the first, attempt to explain the chemistry of respiration. On the subject of heat, its formation, its propagation, its relation to mechanical force and its connexion with vital action there was complete, or almost complete, ignorance. Descartes, indeed, with the present instinct of genius, had put forward the conjecture that heat, like light, was a violent, insensible motion of the ethereal substance pervading the universe. But no proof was offered, no relation of this insensible molecular motion to molar motion was indicated; and the conjecture was buried with many other far cruder hypotheses of this great philosopher, to be revived in our own century. On animal heat the beliefs of physicians were of the most fanciful kind, and were in no respect sounder than those which had prevailed since the time of Aristotle. Descartes—and Harvey seems to have been in the same case—was content with the old view that the heart was a spontaneous source of heat. By this heat Descartes—deviating here from the sounder view of Harvey—held that the blood on entering the heart was expanded, such expansion being the principal motor force which, when the mitral valve was closed, propelled the current of blood through the body. A full century was to pass before Black and Lavoisier were to place the study of heat on a scientific foundation. The second great hiatus rendering a scientific grasp of vital facts impossible was the absence of anything that could be called a science of chemistry. We know life as a series of molecular changes, anabolic and katabolic, old substances decomposing, new compounds arising in their place. This continuous metabolism, following predetermined paths, is the distinctive fact of living organisms; that which most obviously demarcates them from inorganic matter. No event that takes place in a living body, no function of any organ, is

intelligible without it; yet of the chemistry of life Harvey and the generation following Harvey were entirely ignorant. A few metals had been added to the list of those found in the virgin state and known to the ancients, the principal alkalies and some of the mineral acids had been formed and several mineral salts had been investigated, but no step of the first importance had been taken since the time of Paracelsus, and, above all other deficiencies, there was no pneumatic chemistry. In John Mayow, indeed, there was a dim apprehension of the fact that something was contained in nitrate of potash of an ethereal volatile nature akin to the respirable atmosphere and essential to the maintenance both of life and of combustion, and I know nothing more interesting in the history of science than to trace in his works this clutching at the discovery of oxygen which yet eluded his grasp and that of other searchers after truth for a hundred years. The composition of air and water, the difference between air and other gases, remained undiscovered. Combustion was explained by the comprehensive though false theory of phlogiston, the ethereal substance endowed with negative gravity, a theory destined to hold its ground so tenaciously that even Priestley, a century afterwards, could not escape from its shackles. The chemistry of respiration remained unknown. Harvey, to whom both the mechanism of this function and its chemistry were alike obscure, has told us in his printed work, and still more clearly in his manuscript notes, how obscure a problem the whole subject of the lungs was to him, how great an obstacle to his discovery. Before birth the lungs were not needed for the circulation of the blood. Why should they become necessary afterwards?

As the scientific study of life presupposes a clear apprehension of these physical and chemical laws, it is abundantly clear that in Harvey's time a scientific conception of life was not possible. As the art of medicine rests, or at least is ultimately destined to rest, upon biological science, it follows that medicine regarded as a scientific art—an application, that is to say, of scientific principles to particular cases—must have remained throughout the seventeenth and the first half of the eighteenth century extremely crude and imperfect. Nevertheless, in the seventeenth century the attempt was made for the first time to found medical art on such scientific laws as had been then discovered. Harvey was not, perhaps, the conscious originator of this line of action; it was rather due to the stimulating influence exercised by the scientific philosophies of Galileo and Descartes. Still Harvey's discovery of the circulation was unquestionably the starting point from which it proceeded. It is worth while, as I have said, to watch closely the course of this procedure. For if much is to be reaped from the history of truth, something may also be gleaned from the history of error. Of Harvey himself we are told that after the publication of his discovery his practice fell off; the implication being that the propagation of a new truth aroused hostile prejudice and alienated those who had previously consulted him. Is there any valid proof of such alienation? By this College he was from the first held in profound respect; he enjoyed Royal favour so long as there was a king in England. Under the Commonwealth his old age was passed amid every sign of universal regard. I hope it will not be attributed to disrespect of so great a name if I suggest that among the reasons for diminished success in the practice of his art one may have been that his great discovery reacted upon it unfavourably. Had that treasure of his "Medical Observations," to which reference is so often made by him, been preserved to us, we should be able to answer this question with some certainty. As it is, we can but express a doubt whether the dazzling splendour of a new truth may not have brought about a temporary blindness to the old; whether this one function of the circulation, accurately and precisely determined, may not have seemed so overwhelmingly important, by contrast with the nebulous haze in which other functions were still wrapped, that the observer was tempted to account for the myriad phenomena of disease by disturbances of a single organ, and lost his power of regarding the organism as a whole, on which, nevertheless, the art of medicine has rested since Hippocrates, and must for ever rest. If this were so, it was not to be the last time in the history of modern medicine in which the two opposing processes of analysis and synthesis came into disastrous conflict, for that history records analogous reactions on medical practice of almost every important scientific discovery. What happened in Harvey's case we do not and cannot know, but as to the effect of his discovery on subsequent theories of

medicine we are not left in doubt. A school of medicine arose, commonly known as the iatro-mathematical, which numbered many distinguished names, and held its ground for nearly a century, avowedly based on Harvey's discovery, and having for its aim the explanation of vital phenomena by mechanical forces. Some of the most important representatives of this school may be here mentioned. The first on the list is Giovanni Alfonso Borelli, born thirty years after Harvey at Naples, a professor of mathematics and of medicine at Rome and Pisa. He died in 1679. His great work, "De Motu Animalium," appeared the year afterwards. He was the first to analyse distinctly the operation of the muscular system and to attempt to assign with mathematical precision the exact mechanical energy exerted by each muscle. Before his time it had never been realised that the bones were levers and that the muscular tissue was the moving power; the resultant action depending on the angle at which the force was exerted and on the distance of the point of insertion from the centre of articulation. So long as the problem was one of elementary statics he was on safe ground; but many of the problems handled by him needed a higher calculus than was in his possession, and here he made serious miscalculations. The important step was, however, to break ground in this new field, to regard muscular energy as a measurable quantity. Borelli framed a careful and elaborate theory of muscular contractility. The muscle in contracting shortens. What makes it shorten? The first explanation is to compare it with what takes place in a rope when a weight attached to it is lifted, and successive parts of the rope become slack as the work is done; but in the muscle the contraction is simultaneous throughout the whole length. Secondly, the contraction of muscle is not elasticity; this would imply previous extension, and shortening could only take place to the point from which extension started. But, thirdly, can it be said that the contracted muscle is in a state of strain, which being removed the muscle shortens? If so, effort would be felt in the state of rest; while if any exertion was made there would be a feeling of repose. Again, it has been suggested that muscles contract by animal heat, as hair and other animal substances contract on scorching. Of such a rise of temperature there is no evidence whatever. Again, muscular contraction has been compared to the corrugation of worms or snakes, but this corrugation is itself the result of muscular contractions. Finally, he dismisses with scorn the view held by some that the process was not a mechanical one at all, but a vital one. "As though nature," he cries, "could dispense with the laws of destiny fixed by divine wisdom!" What, then, takes place when a muscle contracts? Some bodily substance, he conceived, is transmitted by the nerves to the muscular particles creating an explosion or ebullition, as when oil of vitriol is poured on chalk or water on quicklime. So long as this nervous juice continues to be distilled into the muscle, effervescence goes on, the fibres of the muscle are driven apart as by a wedge, and shortening of the muscle results. When the supply of nervous juice ceases things revert to their former state. Borelli's theory of nutrition was equally mechanical. Over-estimating the force of the heart as a mechanical agent, he conceived the blood as rushing through the vessels with sufficient force, first, to drive away worn-out particles from the tissues and eliminate them through the pores or otherwise; and, secondly, to rebuild the tissues by wedging in new particles adapted to the shape of the pores, just as in mosaic work stones of various shapes are fitted each into its proper place. This sample of Borelli's physiology will prepare us for his pathology. The central fact for the pathologists of that day was fever. What was Borelli's theory of fever? The accepted view was that it was a heat kindled in the heart. A fermentation was supposed to be set up in that organ, the result of which was to set free the spirituous and sulphurous parts of the blood, and thus to bring about the quick pulse and other phenomena of constitutional disturbance. "But where," asks Borelli, "is the proof that the heart is the scene of these chemical processes? What warrant have you for saying that the heart is hotter than the rest of the body? I," he says, "have tested the matter with a thermometer and can find no difference. [This, by the way, is the first instance known to me of the application of thermometry to animal physiology.] As to ferments contained in the heart, the lining membrane," he continues, "is perfectly smooth, and a torrent of blood rushing through it would sweep the imaginary substance away with it. Besides, it is easy to show by injection of hot substances into the blood that heat will not produce fever. No; it is not heat that causes the rapid motion of the blood, but the rapid

motion of the blood that produces fever. My theory of muscular action explains it. The nervous juice is poured out more abundantly into the heart and all the involuntary muscles, and arouses them to increased action. After a time the voluntary muscles cease to be voluntary, and these also are convulsed." Borelli was no doubt obliged to imagine some other cause at work to produce this excess of nervous juice. Either that juice was poisoned by some ferment in the glands which were richly supplied with blood, or the nervous tubules were mechanically obstructed and the fluid contained in them fermented. In any case the visible symptoms of pyrexia—the heat, the swelling, the redness, the pain—were due entirely to mechanical causes. The essential facts in fever were, in Borelli's view, facts of hydraulics. His followers, Lorenzo Bellini and Archibald Pitcairn, carried out the same view in a still more systematic way. Their names may be forgotten now, but in their own day their fame was European. Pitcairn was a native of Edinburgh, and practised medicine in that city, where he was the leading physician, but he had also occupied a chair at two foreign universities of the highest repute, Montpellier and Leyden. In the latter city the illustrious Boerhaave was among his pupils. It is to Pitcairn that Lorenzo Bellini dedicated his work.

Pitcairn's remarkable work, *Elementa Medicinæ Physico-Mathematica*, is a systematic treatise on medicine, beginning as was usual at that time with a statement of physiological principles. This is interesting if only as evidence of the overwhelming importance attached by his school to the discovery of Harvey. Life and the circulation of the blood are identical, he says; life is the circulation; there is no independent life of the parts. It is the body which lives, not any part of the body. Circulation, which is life, depends not on parts but on the whole. "Dividitur corpus in partes continentes et contentas, id est, canales et liquores." Vessels and the contents of vessels make up the whole substance of the body. The differences between one body and another were differences in the fluidity or viscosity of the contained liquids. Then follows his explanation of what was rightly looked on as the fundamental problem of animal heat. He conceived heat to be an explosive substance locked up in certain particles of the blood, and liberated by the attrition of those particles; this attrition, of course, proceeding more rapidly as the circulation was more vigorous. The notion that animal heat resulted from a certain residuum of blood left in the heart and continually fermenting he scornfully rejected, as Borelli had done. There could be, he said, no such remnant. The lining of the heart was smooth, and the whole mass of blood swept through it and passed on. To invoke the chemistry of fermentation was needless. Mechanical causes accounted for the whole. For the pathological fact of fever, or at least pyrexia, mechanics supplied sufficient explanation. "By the word fever," he says, "I understand the velocity of the circulation uniformly increased in equal intervals of time." Increased motion of the blood produces rarefaction, as blood flows more rapidly from capillaries to veins. On rarefaction follows increased secretion of nervous fluid; on this again increased action of the heart's muscular tissue, hence a quicker pulse, so that the effect of increased cardiac action also becomes its cause. The classical symptoms of fever—flushing, swelling, pain, want of sleep, convulsions, hæmorrhage, cutaneous eruption, parched tongue, thirst, anorexia, loaded urine—are each in turn explained as the result of mechanical processes. Intimately associated with Pitcairn was Lorenzo Bellini, one of Borelli's pupils, who carried on the same line of research in an even more systematic way. The problem specially attacked by him was that of secretion, attributed by the chemical school of physicians to the action of ferments. For this school the familiar fact of fermentation, with its attendant phenomena of effervescence—heat, change of substance &c.—did duty as the one solitary representative of the vast domain now known as organic chemistry. It had very naturally and legitimately forced itself upon the attention of those men, offering as it did a prompt explanation of a multitude of obscure facts. The liver was supposed to secrete bile by virtue of its ferment; so did the pancreas, so did the salivary glands, the kidneys, the gastric mucous membrane; nay, as we have seen, the fact of animal heat itself was supposed to be elucidated by an imaginary ferment residing in the heart and acting on the blood as it passed through. Everything could be explained in this way. Men soon become the slaves of words; and so here the word "fermentation" (which in reality held the clue—as 200 years afterwards we have come to see—to some of the hidden secrets of life and disease) became a mere metaphysical figment like

the dormitive influence of opium in Molière's play. It solved hard problems by the simple process of restating them in obscurer and more pedantic language. Against these crude chemical theories the mechanical school of physicians, with Bellini at their head, waged fierce battle. "What sort of an explanation," he asked, "do you arrive at by your theory of ferments? If secretion is caused by a ferment contained in a gland, then what is it that secretes that ferment? Suppose, for instance, that bile is secreted from the blood by some special ferment; that ferment requires a second ferment to secrete it, and that second yet a third, and so on without end." But in truth the whole of this chemical apparatus is, he maintained, unnecessary if we think for a moment what is meant by the cohesion of particles of matter. Two molecules press towards one another with a given force and in a given direction. Change the force and the direction and we have a new arrangement of molecules—in other words, a new compound. To effect this change some external force is needed, but this need not be a ferment; the action is mechanical, not chemical. Secretion is the separation of certain elements of an animal fluid from the rest. Now we see this separation taking place outside the body without these imaginary ferments, as, for instance, after blood-letting, in the separation of the clot from the serum. What takes place outside the body may take place inside. "See again," he continued, "what takes place when blood is placed in a vessel and subjected to Mr. Boyle's new machine for extracting the air. Ebullition, evaporation takes place—that is to say, portions of liquid at once separate from the rest, which had previously been held down in contact with them by the pressure of the superincumbent atmosphere. So it is that inside the body changes of mechanical pressure suffice to explain all that takes place. A gland is simply a closed vessel with extremely small perforations of different shape and size. What takes place in it is as purely mechanical as what goes on in the formation of a blood-clot or the filtering of fine sand from coarse. There is not the slightest necessity for complicating the matter with ferments. *Deus natura conditor est Deus facilitatis* (God does everything in the simplest way)." As time went on the potent mathematical calculus of Leibnitz, Newton and the Bernoullis held out increasing hopes of being able to overtake the subtle processes of nature, and of anticipating direct observation by a reasoning process. Dealing with the infinitely little as well as with the infinitely great, prepared to represent every natural form, even the variations of each human countenance, by an algebraical equation, it seemed to them that they were entering on a path leading directly to omniscience, and surely capable of unravelling the intricacies of life and of disease.

It would be interesting, were there time to do so, and it would not be uninteresting, to trace the influence of this extraordinary scientific stimulus upon the great physicians of the early part of the eighteenth century, more especially upon Boerhaave, a pupil, as I have remarked, of Pitcairn, and upon Richard Mead. In Boerhaave's theory of fever the excited pulse indicated the effort of the heart to sweep away, as by a flood tide, the obstruction in the capillaries, and a similar attempt to explain biological facts by the mechanical forces of the circulation is to be noted in Mead's discussion of the operation of poisons. But these great physicians were preserved by the wise empiricism of their clinical instinct from the extravagances that beset more one-sided men.

Thus it was that the devotees of the two great sciences of mathematical physics and of chemistry—the one brought to a high degree of perfection, the other crude, imperfect, struggling to be born—strove strenuously for their exclusive application to the art of medicine. The intro-physicists were far more fitly furnished than their adversaries with the armament of scientific discovery. They had arisen with Galileo and Harvey; they were carried triumphantly onward by Torricelli and Pascal, by Boyle, Newton and the Bernoullis. The great discovery of Harvey was their own domain; to extend its application to every bodily function was the goal of their efforts. The chemiatic school, on the other hand, could rely only on the sinister though seductive memories of Paracelsus, and on the dawning hopes of a future which they were not to witness. The struggle was watched by a third school of medical investigators, who saw weak joints in the armour of both the combatants—I speak of the animist school, which arose at the end of the seventeenth century under the leadership of Stahl. He was the most prominent chemist of his time. His hypothesis of phlogiston

was accepted as a satisfactory explanation of combustion for three-quarters of a century. But Stahl felt in a confused, dim, strenuous way that the facts of life—the selective, coördinating, prearranging processes presented by the humblest animal or plant—were not to be accounted for by the play of mechanical or chemical forces. So strong were his convictions on this point that his Archè, or Vital Principle, dispensed altogether with mechanics and chemistry. It was a metaphysical figment, involving error at the least as gross as that against which he contended; but within the husk lay the germ of an all-important truth.

Later in the eighteenth century the discoveries of Black, Cavendish and Lavoisier fulfilled the preliminary conditions for the evolution of biology as a distinct science. Haller, Hunter, Bichat and others brought that science to the birth. From that time to this it has become more and more plain that physics, chemistry, biology each has its own domain, its own methods, its own body of inductions, each of the latter terms in the series using the results of its predecessor and adding new results of its own. Life is a structure built up of physical and chemical facts. Yet to the building, to the arrangement, to the ordering of those facts there goes something that neither physics nor chemistry can explain any more than algebra can explain the behaviour of a magnet. To strive to interpret the series of events which make up the life of an animal in terms of chemical metabolism or of conservation and expenditure of energy is an endeavour which will fail; though it is a useful endeavour, because only thus can we eliminate what remains. That something remains the greatest of living British physicists has recently assured us. The admitted insufficiency, to take one instance from a thousand, of Lavoisier's theory of combustion to account for the phenomena of animal heat, the admitted necessity of seeking in the nervous system for a thermotaxic centre or centres to account for the amazing adjustments of the organism to changes of temperature in the environment, were enough to convince the biologist that though he receives his building material from the physicist he must construct the edifice for himself.

The history of medicine is a strange and fascinating though sometimes a melancholy record. We see in the fifth century before our era a man of genius, gifted with that marvellous union of the observing eye with constructive imagination which astounds us in the sculptors of the Parthenon, building up without science, without anatomy, the fabric of medical art of which what we still practise is but the enlargement. Inheriting from the priestly guild from which he sprang a vast store of observations, and adding yet more of his own, Hippocrates was guided in dealing with them by two fundamental principles—(1) that diseases, like other phenomena of nature, follow a natural sequence; (2) that the organism of man, however complex, is yet an individual whole, each part receiving and impressing reactions on every other. After Aristotle and Galen had done their work long centuries ensued of blind and sterile routine, followed by a period of acute but one-sided analysis. By the help of such analysis it may be that the Hippocratic synthesis will be again built up on a more enduring basis. The ideal perfection of medical art rests upon an equally ideal perfection of the science of human nature, summed up in complete knowledge of our organism and of the influences that act on it. The goal is unattainable, yet till it be approached the physician must be content with empirical knowledge of an infinite array of facts—biological, psychological, ethical, which, though certain as mathematics, yet do not admit of quantitative determination. It is only within the last generation that the word "subjective" has become familiar to the biologist. As the student of sensory organs deals with some of these subjective facts, so does the student of human passions deal with others, for these, no less than sensations, are functions of our organism. To determine the way in which this or that man will be affected by any morbid process without taking account of such facts is assuredly impossible. They must be taken into account at all costs; if not by scientific process, then by wise empirical instinct. I shall conclude with saying that as medical art has been affected by the rise of physics and chemistry in the seventeenth and eighteenth centuries, so will it be affected by the scientific sociology of the nineteenth and the twentieth. Not till science has fully embraced every aspect of human life can medical art, as founded upon science, hope to be complete. But at the dawn of modern science in the seventeenth century the dazzling brilliance of mathematical and physical discovery led the keen and daring minds of whom I have

been speaking to the belief that all phenomena with which the physician deals could be spoken of in terms of mechanics. It was a legitimate and inevitable stage in the progress of the human mind. Without it the later stages would have been impossible. It initiated the great discovery of Harvey, whom not merely we, but future generations, will continue to venerate as the principal founder of scientific medicine.

## Lecture

ON

## ANATOMY AS A SCIENCE AND IN RELATION TO MEDICAL STUDY.

*Delivered at the Opening of the Medical Session in the University of Glasgow, Oct. 18th, 1892,*

By JOHN CLELAND, M.D., L.R.C.S. EDIN. &c.,  
PROFESSOR OF ANATOMY AT THE UNIVERSITY.

(Concluded from page 929.)

As in every other branch of science, including the science of medicine itself, so also in anatomy the lowest stage consists of observation, either direct and simple, or aided by artificial helps. This is the stage of "phenomenology," as it has been aptly called; and although deservedly described as not in itself rising to the dignity of science, it is fundamental, all the rest being superstructures whose validity depends on the soundness of the observations on which it rests. It has, moreover, this dignity and educational value, that it requires for its prosecution a faculty which, like every other faculty, must be trained to do good work, and one which cannot be neglected without detriment to the mind as an instrument for discovering truth. The faculty of observation is that by which attention is deliberately bestowed on details appreciated by the senses; by which also they are accurately and consciously recognised and recorded in the memory, so as to serve as data for guidance in further observation. The artisan and scientist train it, each in his own line; but in general education it is very often neglected, while the jaded memory is brought to the front. From observation the mind passes on to reflection; and, just as in the development of the individual mind, so in the growth of every science, the accumulation of facts leads to inquiry into their meaning. Then generalisations and meanings learned as explanations of phenomena demand in turn to be themselves explained, till at last studies which had become more and more distinct as they diverged into territories opening before them meet again as from different sides they are brought into contact with the inscrutable problems of being. But though the progress of science may be analysed into stages, it is not to be supposed that these are practically altogether distinct. Anatomy having come into being in the service of physiology, has busied itself from the commencement with questions of final cause, the uses which organs serve in the economy. It never had a prephysiological era; it was impossible at the outset to consider structure apart from function, and inasmuch as structure cannot have come into developed existence, either in the individual or in its totality, except by the operation of function, any more than function can exist without structure, anatomy and physiology cannot be permanently dissociated. Vesalius saw clearly, and I suppose he was the first to do so, that a temporary retreat from physiological considerations was necessary for anatomical progress. He seems to have appreciated that there was nothing constant in the human body, however purposeless it might seem to be, which was not worthy of close inspection and accurate description. The importance of anatomical fact lay to him in its constancy. Doubtless in later times, heavy and painful description has often been elaborated and taught to students as important, in a way which furnishes a good discipline to them, by men who have simply run in the grooves which others have made who have thought that in carrying elaboration further for its own sake they were making the highest advances possible,—worthy men incapable of looking below the surfaces of things, though full of the peaceful enjoyment which comes to the honest worker. But to initiate a system of elaboration which requires generations to carry out is a different thing, and denotes faith that it will

lead to something more; and this was the position of Vesalius. One of those men who seem to have had a fever for hard work, directed even in boyhood to anatomy, he was capable of enjoying the luxury of the courts of Charles V. and his son Philip of Spain, and leaves evidence in the truly wonderful illustrations of his masterpiece, "De Corporis Humani Fabrica," of a keen enjoyment of artistic beauty of form and the appreciation of it as pervading internal structure. But the work stands out mainly as a monument of a new idea of precision of observation and accuracy of detail, contrasting with what went before and laying the foundations of descriptive anatomy apart from physiology.

It is not till modern times that we find anatomy rising to the conception of a rational morphology. It is only in modern times that the word "morphology" makes its appearance. During the last decade or so it has been a good deal employed in an altogether unnecessary way as a mere synonym for anatomy as opposed to physiology. Such a use of the word is to be condemned. The word is not morphography, but morphology, and means not the description of forms, but the study of their relations one to another—morphological and not topographical relations. These relationships are of different kinds. There is a symmetrical correspondence of right and left sides, obvious to the eye but as yet never grappled with in its causation. There is sexual correspondence, or the fundamental identity of organs differently developed in the two sexes, a correspondence to a certain extent vaguely appreciated even by the old anatomists. More remarkable are two other kinds—viz., the serial correspondence of different parts in one animal and the correspondence of parts in different animals. One digit manifestly repeats another. The lower limb also manifestly repeats to a considerable extent the upper, and the mind is led on to compare the two more and more in detail. Architectural harmonies throughout the whole body become apparent—in some instances so obvious that at first it does not seem necessary to remark upon them; in others so questionable that further research is required to ascertain if they are real; and even when a correspondence undoubtedly exists there may be questions as to its details. For example, a part of the hand obviously corresponds with the heel; but it requires a good deal of investigation to settle precisely how much of the hand corresponds with the heel-bone. These inquiries cannot be successfully carried out unless we look at corresponding structures in different animals, and it is a matter of fact that it was only when comparative anatomy came to be systematically studied that these inquiries began to be made. Besides this, it is really the same sort of task to make a just comparison of the bones of the skull of a fish with those of the human skull as it is to arrive at the morphological relations of the skull to the vertebral column in man. Thus, pure human anatomy rises to a higher than a mere observational stage, and leaves physiology for a time only to find itself part and parcel of a larger science of which the study of the lower animals forms a necessary portion. At this stage it has not reached its highest level, but it has gained a vantage ground from which the mind is influenced in its whole conception of animated nature. There springs up, as there sprang up before the eye of Geoffroy St. Hilaire, a vivid view of what he called the unity of organisation—a unity which has to be recognised in many details before the questions can be profitably asked, "How did such unity come to be, and how did the objects come to exist in which it is exhibited?"

Doubtless the same unity in variety which is studied in homology of structure pervades other things as well. Time and chance have their influence on everything, and the researches of the philologist into the origins and affinities of words and languages display in like manner the derivation of the complex from the elementary and of dissimilars from common origin. Perhaps simpler illustrations of gradual variation, evolution and degeneration are furnished by the history of architecture, and illustrations even more familiar are abundant in the history of dress. The hats, coats, and boots of the present day cannot be accounted for without knowing those which have preceded them and the influences which have operated to produce change. Perhaps you think that because fashion is largely founded on caprice its changes are sufficiently accounted for by attributing them to that cause. But caprice itself is subject to law—namely, to the causation of antecedence and environment, and every shape of garment is descended from another which leaves its mark on it. The lapels of dress-coats, with useless nicks and jagged points and impossible button-holes without buttons to match, are the vestigial

remains of fronts which buttoned across the chest, collars that protected the neck, and the space left for the chin when the breast was buttoned and the collar up. Thus, also, there is not a discovery, not an act, not a thought which is not evolved from its antecedents, both external and internal to the thinking agent; but the homologies of living structure, whether animal or vegetable, have their special interest in being, not the result of the succession of human ideas, like the homologies of words and clothes and buildings and many other things, but part of the order of growth by which the organisms exhibiting them exist. There are three ascending series of forms which demand attention in the prosecution of the higher anatomy—viz., first, that passed through from the earliest stages of existence, the embryological series; secondly, the adult forms at present existing, from the lowest to the highest, constituting the comparative anatomy series; and, thirdly, the forms existing in different geological epochs—the palæontological series. The last is so imperfect at the best, and so almost disappeared as regards soft textures, that its relics stand out only as guides to what has been when they are translated by that which now exists. Thus it is present forms which in their adult diversities and their more similar early stages furnish the field from which the data for the higher anatomy are derived. Not otherwise than with eyes ready to consider all can the purely morphological investigation of the architectural meaning of parts be properly carried on and the steps of evolution from the simple to the complex be rightly understood. But pure morphology is not the final goal of anatomy. The history of the body is not completed when the stages through which it has passed have been described and its parts have been compared one with another and with those of other organisms. The recognition of stages and resemblances opens up questions of causation. What is it which effects from the ovum the development of the aggregate of millions of shapely structures constituting the organism into one shapely and finely determined whole? The starting of such an inquiry leads to another important, though much smaller, question, Is there any genetic bond of relationship between different kinds of organisms? This latter question is now universally answered, or almost universally, by biologists, in the affirmative, not because the answer can be proved, but because scientific probability points altogether in that direction. It was raised and answered in the affirmative by Lamarck and St. Hilaire, and the affirmative answer has become popular since Darwin wrote. But the genetic connexion of different beings, when established, only presents us with a development or a series of developments through the ages which is comparable with the development of the individual adult from the ovum. It makes it all one genesis with which we have to do, but it still remains to investigate the causation which, carried down from parent to offspring, in a manner called heredity, passes through the narrow channel of a fertile ovum and moulds different beings to their shapes. Such a tremendous problem is naturally liable to be attacked piecemeal, and more or less partial solutions have been offered at different times in Lamarck's theory of appetency, Darwin's theory of natural selection and Weismann's hypothesis already nearly shelved. These theories all deal with heredity, but none of them can be said to give any idea of what the source of heredity is. It is a common notion among biologists that the whole secret of life is to be explained by the operation of the laws of dead matter, and those who hold this notion think it highly philosophical, but neither the physical nor the chemical laboratory reveals any phenomenon similar in kind to organisation, reproduction or heredity.

There are two propositions which I shall now lay down; both of them are founded on purely anatomical data, and already made familiar to some of you in the class room. I claim them as my own, and think it is important to keep them in view in investigating the causation of life. The first does something to simplify, though not to explain, the problem, and is that all segmentation or metamerism, animal or vegetable—all serial homology—is simply a variety of reproduction; that process which in its simplest form converts a unit of texture or a unicellular organism into more than one, and in the form known as gemmation or budding of complex organisms presents not a single corpuscle resolving itself into a number, but an undifferentiated mass of corpuscles resolving itself into repetitions of the forms from which it sprang. My other proposition, already laid before the scientific world, is that the organising power, including heredity, is in vertebrate animals demonstrably not resident in the individual living corpuscles of which the embryo is composed, but in masses of these. The demonstration comes from the study

of malformations, from instances in which heredity is opposed by mechanical obstacles, and I shall on this occasion take for example the development of the eye in cyclopia, that curious form of development in which an eye is placed, not indeed in the forehead, as in the fabled cyclops, but underneath the nose. The seniors among you know that the eyes take origin separately one from another. But in cyclopia there is a single mesial eye, shapely, though not perhaps perfect in all details. The masses which ought to have produced two eyes, being mechanically prevented from moving outwards, produce not two imperfect eyeballs crushed together, or intercalated one with the other, but a single symmetrical globe with muscles arranged around it, and often with a perfect cornea. This is only one instance among many of the same kind showing that masses of corpuscles act consentaneously, ordered by some pervading influence different from the chemical or structural composition of each. Therefore, *life is not, as has been alleged, a mere property or set of properties, chemical or other of protoplasm.* Life, mere organic life, is not an evolution of the properties of the chemical elements; it is something more, a new order of things made manifest on the earth.

I pursue this subject no further at present. My object has been to show by illustration from anatomy the stages of advance of a division of natural science,—how, devoting itself in the first place steadily to intricate details, it deals as it progresses with high and varied problems and becomes more and more evidently a factor in philosophy. I have done this that you who are students of medicine in this university may see how the hand of Medicine herself beckons you on to the largest and deepest inquiries, to a culture of the mind and a recognition of the universe second to none that can employ the intellectual powers.

ABSTRACT OF THE

## Introductory Address.

Delivered at Anderson's College on Tuesday, Oct. 18th, 1892,

By W. L. REID, M.D., F.F.P.S. GLAS.,

PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN AND CHILDREN,  
ANDERSON'S COLLEGE, GLASGOW.

[THE lecturer introduced his subject by recounting the early career of Dr. William Smellie, whom he regarded as the type of a truly successful medical practitioner, and the prominent features of whose character formed the gist of the address.]

1. Smellie did not believe that poverty was a barrier to success. We find careful notes of cases dated 1722, within a few months after he began practice, and there is something touching in the idea of this man courting science so assiduously, while yet obliged to sell cloth to keep himself in daily bread. Afterwards, when a somewhat scurrilous opponent, amongst other charges, taunted him with the fact that he had at first to advertise his lectures on a street lamp, he took pains to refute thoroughly the more serious charges, but was not concerned to deny that poverty had compelled him to resort to such a device. I have known many students who were ruined by having too much money; very few, indeed, through having too little.

2. Smellie was a man of great industry. We see this from the elaborate and accurate notes he took of his cases, as well as from the fact that he taught midwifery clinically by attending cases of labour with his pupils, in whose presence he delivered 1150 women during his first ten years of teaching. I know something of the labour involved in work of this sort amongst the poor, and we have evidence in the details of his work that time and labour were not much thought of when expended for this purpose. He was not industrious by fits and starts. His record of cases for the forty years he was in practice is almost uninterrupted except during the year 1739, when he was searching in London and Paris for further instruction in his favourite subject. According to the views of certain people Smellie should have spent one evening a week at the theatre and another at a music-hall, or what in those days represented such. In my opinion

he did better. He varied his usual work by studying music and painting as personal accomplishments. Thus, in his will he left to the Lanark Library, which he founded, "nine English floots with the thick 4to gilt music-book," and the only known portrait of Smellie is an oil painting now in the possession of the Royal College of Surgeons, Edinburgh, painted by his own hand. Again, his obstetric plates, of which the late Dr. McClintock of Dublin says that they "have been universally admired for their accuracy and their execution, in which important particulars they far surpassed anything that had ever appeared before and have seldom been equalled since," are known to be partly his own work, as he speaks of having been "assisted" with them by Dr. Camper, Professor of Anatomy at Amsterdam. I should advise you, gentlemen, especially while you are students, to copy Smellie in his steady work. It is true that a clever man may put on a spurt towards the end of a session and distance his fellows, but the greatly safer plan is to keep well abreast of your work by doing the day's work every day. No less would I advise you to have some relaxation, but let it be one which need not take you out of your own rooms in the evening, the evening hours being, at least for the medical student, those in which he has most opportunity of reading steadily. The late Dr. John Brown of Edinburgh thought that a doctor's relaxation might wisely be literary in its character. "I like to show," he says, "that our medicus may be not only, like Locke, at once a good physician and metaphysician, or, like Adams, equally great as a scholar and a domestic 'leech,' but that he may be a poet too."

3. Smellie was an enthusiast in his work. Our world at present is cursed with half-hearted workers, men who occupy positions and profess to do work in which they have little or no interest. The man of whom we are speaking was not of this sort; indeed, in his heartiness he was occasionally betrayed into making statements that sound self-laudatory. Thus, in speaking of "phantoms" and "dummies" as we now call them, he says: "I considered that there was a possibility of forming machines which should so exactly imitate real women and children as to exhibit to the learner all the difficulties that happen in midwifery, and such I actually contrived and made by dint of uncommon labour and application." A pamphlet was published in 1773, directed against the practice of midwifery by men, which practice Smellie had strongly supported. Yet this antagonistic author felt bound to speak of Smellie as an individual in the following terms: "I knew him well ..... he was an honest man ..... and, what ought to recommend him and enforce his authority with those of his fraternity, he was an enthusiast in his profession. Man-midwifery was the idol of his heart; he believed in his forceps as firmly as he believed in his Bible." Dr. McClintock, in giving this quotation, adds: "The indomitable perseverance he displayed in very many of his operations is most remarkable, and, considering the strong popular prejudices then existing against instruments and male practitioners, it must have required no small degree of moral courage and confidence in his own resources to have acted as he did." If any of you, gentlemen, find, as you go on with the study of this profession of medicine, that for you it lacks real interest and that you look forward to its practice simply as a means of earning a living, I forewarn you that you may look forward also to a life of comparative drudgery; for, unless brightened by real interest, the work will be found hard to a degree.

4. Smellie's thoroughness was remarkable, and this, of course, followed on the heartiness with which he did his work. In the preface to his volume of lectures he says that he hopes the reader will not imagine that it was "cooked up in a hurry," and informs him that he had taken six years to write it and that it had been "from time to time altered, amended and digested." What a boon it would be to us students and practitioners if all authors of medical books could say this truly of their productions. Dr. McClintock, in his memoir of Smellie, and in its very first words, refers to this matter of thoroughness. "As a teacher, author and practitioner there is no British obstetrician—certainly none of the eighteenth century—who deserves so high a place in our estimation as William Smellie." Is there not an important lesson for us here? How can a man do effectual service to his neighbour or raise himself in his own estimation if he knows in his heart that his work is done in a slipshod slovenly manner? Let us, then, determine firmly—for we must all find it a difficult task—to do to the very best of our ability what duty brings to our hand.

5. Smellie had great power of observation, which is usually

another way of saying that he had carefully trained himself to get at facts, to see things not as they seemed but as they actually were. He, like all men who have done good, original work, believed in a constant appeal to nature. Dr. McClintock says of him that "he was a keen and accurate observer of nature and exercised the utmost care in obtaining correct data on which to found his conclusions. Here was the secret of his unrivalled success as a reformer and improver of midwifery." Rigby also, in the preface to his translation of Naegelé's "Mechanism of Parturition," says that "any person who has devoted his attention to midwifery and is at all acquainted with the history of this branch of the medical profession must acknowledge the immense advance it made during the beginning and middle of the last century in the hands of Smellie and others." In this respect, gentlemen, we shall all do well to imitate Smellie. Let us learn carefully to observe facts, note them as carefully and not less carefully reason from them afterwards. In this way we may hope to rear on the foundations laid by those who have gone before us a superstructure of abiding truth. Dr. John Brown had strong views on this subject. Writing near the end of his eminently thoughtful life he said: "Although recognising fully the immense enlargement of our means of knowledge in these latter years, I would put in as strong a word as ever for the cultivation and concentration of the unassisted senses. Microscopes, sphygmographs &c. are good, but do not let us neglect the drawing out into full power by the keen and intelligent use of them those eyes which we can always carry with us."

6. Smellie was very disinterested, generous in his disposition and ready to give credit to others for their good work. Thus in connexion with his knowledge of obstetrical instruments he said: "In particular I was obliged to Dr. Gordon of Glasgow and Dr. Inglis of Lanark in Scotland; the first made me acquainted with the blunt hook, the other with the noose; and in London, Dr. Nisbet assisted me in improving the forceps, and Dr. Hunter in reforming the wrong practice of delivering the placenta." One of his old pupils remarked of Smellie that "no man was more communicative without the least self-sufficiency or ostentation." It is difficult to estimate how far his good influence went, for, amongst many others who afterwards became more or less famous, he taught William Hunter and Denman, Dr. McBride of Dublin and Professor Roederer of Göttingen, and through them hundreds of their successors. Smellie was at first bitterly opposed by the midwives and many of the medical men of London, and I could give no end of amusing instances of their more or less disguised attacks on men midwives in general and him in particular. A big female practitioner in London in those days was Mrs. Elizabeth Nikell of the Haymarket, who in 1760 published "A Treatise on the Art of Midwifery." A few extracts from her "Treatise" will give you some notion of the kind of opposition Smellie had to encounter in the introduction of the forceps and improved methods of delivery in general. Thus she sought to bring his phantom and dummy into ridicule in the following passage: "This was a wooden statue representing a woman with child, whose belly was of leather, in which a bladder full, perhaps of small beer, represented the uterus. This bladder was stopped with a cork, to which was fastened a string of packthread to tap it occasionally and demonstrate in a palpable manner the flowing of the red-coloured waters. In short, in the middle of the bladder was a wax doll, to which were given various positions. By this admirably ingenious piece of machinery were formed and started up an innumerable and formidable swarm of men-midwives, spread over the town and country. . . . I hope, too, that it is an injustice done to that doctor by those who say that his pupils have too often a way of hurrying out the waters, which can only serve to render the labour more dry, consequently more laborious, and by that means furnish a handle for setting their instruments to work." Again, in advising ladies as to what kind of practitioner they should employ, she says: "If, on the contrary, and what the most frequently happens, you fall into the hands of one of the common men-midwives, either of that multitude of disciples of Dr. Smellie, trained up at the feet of his artificial doll, or, in short, of those self-constituted men-midwives, made out of broken barbers, tailors or even pork butchers (I know myself one of this last trade, who, after passing half his life in stuffing sausages, is turned an intrepid physician and man midwife), must not, I say, practitioners of this stamp be admirably fitted as well for the manual operation as for the prescriptions?" That this lady

had a vein of genuine sarcasm may be observed in the following quotation: "But if it is not too presumptuous for me to offer so learned a gentleman as the doctor a hint of improvement for his man-practitioner's toilette, upon these occasions I would advise for the younger ones a round-ear cap, with pink and silver bridles, which would greatly soften anything too masculine in their appearance on a function which is so thoroughly a female one. As to the older ones a double clout pinned under their chin could not but give them the air of very venerable old women." Of the calling of obstetrics, as practised by men, it is said to be "an upstart profession, sordidly mean in its motives, infamously false in its pretences, shamefully ridiculous in its practice, and yet dreadfully serious in all its consequences." "Yes, an ignorant midwife, without perhaps anatomy enough to know where the *pineal gland* is, or without so much as having heard the name of the *ossa innominata*, and with purely her expertness, and with that sort of knowledge she has at her fingers' ends, will give you a more useful and practical account of matters as they go, where it is sometimes so infinitely important to know how they go, than the most learned anatomist that ever dissected a corpse, brandished a forceps, stuck a crotchet into a child's brain-pan, or tore open a living woman." These quotations may serve to give us some idea of the difficulty, and even danger, to which Smellie exposed himself in delivering poor women instrumentally in those days, and it is a matter of fact that, but for the happy termination of some of his cases, he would have suffered bodily injury at the hands of the mob.

7. Smellie had a high idea of the dignity of his profession. In speaking of the efforts of himself and others to improve the different forms of obstetrical instruments, he adds, evidently referring to such men as Roonhuysen and the Chamberlens, who had concealed their inventions of the vectis and the forceps from their medical brethren, "I hope every gentleman will despise and avoid the character of a secret-monger." Let it be your ambition, gentlemen, should you be fortunate enough to discover any new means of relieving weakness and pain to make such known as widely as you can, so that the honour of our profession may be sustained and suffering humanity benefited. Be sure that in some shape you will not lack your reward.

To sum up, gentlemen, I would advise you to consider carefully whether you are carrying on your work as medical students *con amore*, and if not to turn to something more congenial. Next, to make up your minds to work steadily with wise and reasonable relaxation, holding in view that the relaxation may possibly be made such as to subserve your professional progress. Perhaps some of you may meet me with the assertion that there are now so many "ologies" to be learned that one has no time for relaxation. Well, there is some truth in this, and you must exercise your judgment as to how far you should go in prosecuting such studies. My own belief is that a steady worker can easily go as far as the pass examination demands and yet have time for sufficient relaxation, both physical and mental. Dr. John Brown, whom I have already quoted, had no great faith in theoretically over-educated medical students. He recommends men to study vigorously the essentials of their profession, so as to get them well by the back, not meanwhile overloading themselves with the "ologies," but afterwards when time and opportunity offer studying those interesting and important, but less practical subjects. "Often," says he, "when I see some of our modern Admirable Crichtons leaving their university armed *cap-à-pie*, and taking the road, where they are sure to meet with lions of all sorts, I think of King Jamie, in his full armour—'Naebody daur meddle wi' me, and, with a helpless grin, 'I daur meddle wi' naebody.'" We may differ from Dr. Brown when he asserts that a man too full of certain kinds of knowledge may be thereby incapacitated for effective everyday work; but we can hardly differ from him when he says that "sagacity, manual dexterity, cultivated and intelligent presence of mind, the *taotus eruditus*, a kind heart, and a conscience—these, if there at all, are always at hand, always inestimable; and if wanting, though I speak with the tongues of men and of angels, I am as sounding brass, or a tinkling cymbal; and though I understand all mysteries and all knowledge, I am nothing." I can profit my patient and myself nothing." Smellie in the introduction to his "Treatise on Midwifery, after reviewing the work of those who had gone before him and pointing out the fact that with their limited opportunities they had done wonders, concludes with some observations which I also, in concluding, commend to

you and myself for careful consideration: "True it is we have established a better method of delivering in laborious and preternatural cases by which many children are saved that must have been destroyed by their manner of practice; but are not many modern practitioners justly branded for their sordid and unsocial principles in professing nostrums, both with regard to medicine and methods of delivery? Insomuch that I have heard a gentleman of eminence in one of the branches of medicine affirm that he never knew one person of our profession who did not pretend to be in possession of some secret or another; from whence he concluded that we were altogether a body of empirics. Such reflections ought to make a suitable impression upon the minds of the honest and ingenuous, prompt them to lay aside all such pitiful, selfish considerations, and for the future act with openness and candour, which cannot fail of redounding to the honour of the profession and the good of society, as well as their own advantage."

---

ABSTRACT OF THE

## Inaugural Address

*Delivered at the Opening of the Session at St. Mungo's College, Glasgow,*

By D. C. McVAIL, M.B. GLAS.,

PROFESSOR OF CLINICAL MEDICINE AT THE COLLEGE.

I HAVE the honour to bid you welcome to this College on this first day of a new session. The work you will be engaged in and the manner in which you will do it is of the greatest importance to you now, and in the near future will be of importance not only to you, but to countless numbers of your fellow men and women. You will have the lives of your patients in charge, and no human responsibility can be greater than that. The field of medical study overlaps, in part at least, every department of scientific knowledge. Physics, chemistry, botany and zoology you must master in their broader features and in many minute particulars. When you have acquired a sufficient knowledge of these four preliminary and vast subjects you will then proceed to study the structure and functions of the human body. Not much more is known of macroscopic human anatomy than was known fifty years since, but you must study it with far greater precision than until recently was required, for since the inauguration of aseptic surgery by Lister many more regions of the body have come within the scope of operative surgery. Physiology, unlike anatomy, has advanced and is advancing with ever-increasing strides. Thirty years since a man would have been dull who could not have disposed of "Kirkes' Handbook" in a fortnight, but you will find that the nine months you will devote to the subject by no means too long a time for what you have to do. When from anatomy and physiology you have learned much concerning the human body in health you will then proceed to the great and modern science of pathology—a science that, as known to us, has been created in the lifetime of men still living. Pathology will teach you the essential nature of the modifications of structure and function which constitute the basis of disease. Get a firm grip of pathology, and let me tell you there is no institution in the kingdom where the opportunity of doing so is greater than in this hospital and school. At the same time that you are engaged with pathology you will also be engaged in a study of a very different kind. You will be in the class of *materia medica* and you will be amazed at the number and variety of the substances that are or have been in recent times in use in the treatment of disease. When you have completed attendance on these four great subjects which form the second group of your course of study, you will enter on the final subjects of the curriculum—systematic medicine and surgery in the class-room and clinical medicine and surgery in the wards; and by the new regulations of the Medical Council your fifth year must be entirely clinical and practical. The enormous importance attached to clinical teaching now is in complete contrast to the perfunctory methods of by-past years. You shall not walk the hospital as men of only thirty years since did. They came

and went as they pleased and got their certificates by merely writing their name once every two months in the infirmary album. In your fourth year, in addition to systematic medicine and surgery, you will have midwifery and gynecology and forensic medicine; and in your fifth year, besides ordinary work in the wards, you will have many special departments to attend.

The Royal Infirmary is a hundred years old. When it was opened the Hunters were but recently dead, and the greatest work of the greater of these brothers—that of "Inflammation"—was as a posthumous work not yet published. Their famous nephew—Matthew Baillie—was on the eve of printing his great work on "Morbid Anatomy," the pioneer of so many books on that subject that have come since. The stethoscope was thirty years away in the future, together with the marvellous clinical and pathological observations on pulmonary conditions by its inventor, Laennec. Mediate percussion was thirty-five years in the future. Rude forms of the microscope had been employed by a few, a very few, physiological investigators, but to hospital practice it was as foreign as the telescope. It was not until 1829 that the elder Lister made the microscope achromatic, before which time there was little accuracy in its revelations. Lister's invention was the necessary forerunner of physiological and pathological histology, and eight years afterwards the first important contribution to the subject was made by the publication of the famous paper entitled "Contributions to Phytogenesis," by Schleiden, where, for the first time, was demonstrated the cell structure of plants and the cell shown to be the ultimate rudiment of life. Next year, 1838, the second great step was taken by the publication of Schwann's "Microscopical Researches into the Structure and Growth of Animals and Plants," in which he demonstrated that in animals also the cell is the ultimate unit of life. The application of the cellular theory to pathology necessarily followed, and Goodsir of Edinburgh was the first to direct attention to cell alterations as constituting the fundamental phenomena of disease. Virchow followed in the lines of Goodsir's suggestions, and by the force of his perseverance and genius created for us the pathology of the present day. An early contemporary of Virchow, the late Professor Bennett of Edinburgh did for a time brilliantly oppose the cellular theory of physiology and pathology, and proposed in opposition to it his own molecular theory of organic structure. That did not long engage the attention of histologists; but recently in another form it is again forcing itself into consideration, particularly in recent observations of the changes that occur within cells that are about to divide and multiply.

About the year 1620 Harvey demonstrated the circulation of the blood, but until the time of the Hunters there was little further contribution to the inductive observation of the vital actions and processes in health and disease. John Hunter was the first of the modern school of physiologists and pathologists, but your predecessors in the early years of the Royal Infirmary could form but little idea of the far-reaching consequences of John Hunter's work. Baillie, in his "Morbid Anatomy," tells all that was really known of pulmonary disease up to 1793, and all he has to say could be read in an hour and might be remembered by reading it once. This hospital was twenty-six years old when Laennec was appointed to the Necker Hospital in Paris, and two years thereafter he published his immortal treatise on the "Diseases of the Chest," and for the first time then the students of this hospital began to be taught the broad outlines of pulmonary disease in many respects not greatly different in their clinical aspects from the manner in which you are taught them now. In 1825 his teaching was supplemented by the invention of mediate percussion by Piorry. From that time the advance of knowledge regarding pulmonary disease was not very great until the development of bacteriological research and the discovery of the tubercular bacillus by Koch and the pneumonic micrococcus by Friedlander and others. All our authorities on diseases of the nervous system have been men of the present generation—Brown-Séquard, Duchenne, Erb, Hitzig, Ferrier, Hughlings Jackson, Macewen, Victor Horsley and many others, and most of them are still alive. Before the invention of the stethoscope little was known regarding diseases of the heart. To Laennec again we owe the beginnings of our knowledge of abnormal cardiac conditions, but here he was far less successful in disclosing the secrets of disease than in the case of the lungs. Our cardiac knowledge is derived from many sources. We are perhaps more indebted to the treatise of James Hope, published

in 1832, than to any other source, and it was a great discovery that of Peter Latham, when he first demonstrated in 1826 to the students of St. Bartholomew's Hospital the connexion between rheumatism and peri-endocarditis. If there was one department of disease more than another in which our predecessors might have handed down to us accurate information it was that of the contagious fevers, for they had opportunities of studying these that fortunately for you are now greatly circumscribed. In the early years of the century all great towns were hotbeds of fever, but half of the century was yet to elapse until in 1850 Sir William Jenner finally established the difference between typhus and typhoid. The effect of isolation of contagious fevers has only been carried out effectively within the last two decades.

How vast, then, is the change, development and expansion of our knowledge of disease since the first medical students of the University of Glasgow and the extra-mural teachers in College-street began to study in the wards of the Royal Infirmary. The change entails vastly more work on you, but that I am sure you will not grudge. But here the question arises, Has there been an expansion in our ability to deal with disease at all commensurate to our increased knowledge of the symptoms and pathology of morbid conditions? In surgery beyond all dispute the advance in operative and non-operative treatment has been immense. But in the diseases with which the physician has to cope the answer is much more doubtful. In the first half of the present century one-half of the total expenditure of the Royal Infirmary in the department which supplies to the physicians and surgeons all drugs, agents and appliances of treatment—one-half of the total expenditure—was for leeches. I think it questionable if to-day there are a dozen leeches in the house. Bleeding was then a universal panacea in the treatment of disease in every form. Every doctor carried his lancet and every doctor performed vivisection every day of his life. He bled on his first visit, and the blood drawn was kept for his inspection on his return, and if it had a buffy coat—and it generally had—he bled again. Vivisection, leeching and cupping were in continual use until after the first half of this century had passed away. Besides leeching there was starvation; besides starvation there was mercurialisation; in almost every illness the production of salivation was reckoned necessary. At the beginning of all acute affections emetics were indispensable. Antimony was in daily use, and in such a disease as pneumonia it was continued from beginning to end. Only when the patient was given over as hopeless were feeding and stimulation permissible. No wonder, then, that so many diseases were regarded as dangerous which we now can confidently hope to see cured. Pneumonia in our day is generally amenable to treatment. In the early part of the century the mortality was more than 30 per cent. In this country we are indebted chiefly to Bennett of Edinburgh and Todd of London and Graves of Dublin for our awakening and true estimation of the evil treatment of disease. Graves said "Feed fevers," Bennett, in effect, said "Feed everything," Todd said, "Stimulate everything." In a few years the reaction was in full swing and possibly went a little too far, particularly as regards stimulation, and to no one more than to Gairdner of Glasgow are we indebted for a moderating influence in the use of alcohol in acute disease. We have got rid of emetics. We seldom salivate and we do not use depressants, and the actual cautery and Corrigan's button have no longer a place in the instrument bag of the physician. But if we have ceased to do harm how much good do we accomplish? In the meantime the wise physician gives much scope to the *vis medicatrix natura*. He gives his patient rest, he gives strength by judicious feeding and stimulation, he relieves pain, he procures sleep where he may, he lessens cough, he promotes digestion where that is necessary, and, in addition, he attempts to deal, with what success he may, with symptoms as they arise, and as far as he can he endeavours to restore organs to a better performance of their functions. He has an enormous pharmacopœia of drugs at his disposal, but he is chary in his employment of it. The good physician of the present day is most emphatically a student of the action of drugs—I say the good physician, for it is too much the custom so to combine drugs in prescriptions that it is impossible to decide as to the particular action of any one of them. Every year some new drugs are brought under the notice of the profession with a certainty of statement regarding their use which is most captivating, and every year almost as many recent remedies cease to be used by the profession. The very aptness of the profession to employ new remedies on the most slender basis

of fact demonstrates the unsatisfactory condition of drug-giving as a whole.

What the profession at large has yet to study is the natural history of disease—the course of a disease when no drugs are used. Fortunately we now know that well in so far as acute diseases are concerned, but we know it far less well when the course is chronic. In acute disease few drugs are given, and they are chiefly given as tonics or stimulants; but in chronic affections the physician is apt to ring the changes through a great part of the pharmacopœia. In acute diseases he trusts to the *vis medicatrix natura*; he rests, feeds and stimulates his patient according to the condition of his general strength. In chronic disease he drugs his patient, and often with results that are unsatisfactory. And yet in many instances chronic disease differs from acute disease only as regards the time occupied by the processes of structure and function. Nature tends to stability of type and structure.

Few physicians now alive deserve greater honour than Sir George Johnson. He has devoted a long life and a powerful mind to the study of diseases of the kidney, and particularly its chronic diseases, and he is now able to tell us that many forms of these chronic diseases are amenable to treatment. How general is the impression that fatty cells and casts appearing in the urine necessarily mean incurable disease of the kidney; and yet Sir George Johnson has shown that a patient may have albumen in large amount, anasarca and dropsy and fatty cells and casts, even, for years, and yet that there is possibility of cure. How does Sir George Johnson treat the case. Merely by rest and a milk diet; and that in the firm belief that just as the racehorse and drayhorse of Darwin will, in the absence of the circumstances that have produced their special features, and with sufficient time, revert to the original type, so will the cells and tubes of the diseased kidney revert to their original type and structure in the prolonged absence of the causes which brought about a departure from normal type and structure. For many years to come the practice of medicine must be experimental, and the more you deal with it inductively and the less you deal with it deductively the better. It is by observation and experiment that we have arrived at our present position, and it is only by observation and experiment that we shall make further advances.

In all times the human mind has associated great deeds with the localities where these great deeds were achieved. The spot on which we have now assembled and its neighbourhood have for many centuries been distinguished for achievements many of which have influenced the whole life of the country and some that have profoundly affected the whole civilised world. Three movements of world-wide influence began within the walls of, or in direct connexion with, the University of Glasgow. The first of these was the inauguration of popular scientific and technical education by Professor Anderson about 1758. He invited the mechanics of Glasgow to attend the experimental lectures in his course of Natural Philosophy, he admitted them without fee, and not only did he open his doors to them, but he visited their workshops and specially invited them to attend; and that this work of popular scientific instruction might not come to an end with his life he bequeathed his apparatus, library and his money to found a college expressly for the purpose of continuing it. Anderson's College, both directly and indirectly, has more than fulfilled the expectations of its founder. The second event of world-wide importance that occurred in the old college was the invention of the condensing steam engine by Watt in 1765, an invention that has revolutionised the life of mankind. The early development of this invention, that has placed at the disposal of man the material wealth and resources of the earth, ran concurrently with the working-out of the third great contribution of world-wide importance by a Glasgow professor—the "Wealth of Nations," by Adam Smith. Watt gave to the world manufactures and commerce; Smith laid down the principles on which these were to be regulated and worked between individual and individual, between class and class, between nation and nation. It was in the year when the first perfected engine left the Soho Works of Boulton and Watt at Birmingham that Adam Smith's book was published. The coincidence was marvellous. From standpoints of thought far distant from each other the two men laboured, but what the one did was the complement of what the other did. Their combined work began a new era in the world, and the one was mechanist to the college, and the other was its professor of moral philosophy. If the shade of Pope Nicholas can revisit the world he may bemoan

the suppression of the archiepiscopal see, but certainly he will not regret the survival of his "Studium Generale."

After the line of archbishops came to an end the great castle they had occupied fell gradually into decay. In its courtyards children played, and in one of them a booth was erected where the first theatrical performances in Glasgow took place. But somewhat more than a hundred years since the ruins were removed to make way for the erection of the Royal Infirmary. The site where for many centuries the spiritual wants of the community had received consideration and care was now to be devoted to the treatment of their physical infirmities. Although more lowly in station the physicians and surgeons of the Royal Infirmary have been on the whole fitting successors to the ancient bishops. At first a hospital for eighty patients, the Royal Infirmary now accommodates 586, and soon provision must be made for more. Since its foundation many thousands of students have received clinical teaching in its wards. In every county in the kingdom, in every country in the world, you can meet members of the profession who studied in the Royal Infirmary. In the century that has elapsed since the building of the hospital its staff has contributed much to the advancement of medicine and surgery. Dr. Andrew Buchanan first demonstrated in these wards the causes of the coagulation of the blood and first introduced the operations of plastic surgery. The late Dr. Perry did much to prepare the way for the final differentiation between typhus and typhoid fever by Sir William Jenner. Dr. Morton here first performed his glycerio-iodine injections in spina bifida. Mr. Macewen here first attempted his operations of osteotomy, his transplantation of bone and his work in cerebral surgery; and in the Royal Infirmary Professor Lister inaugurated the methods of aseptic surgery, the greatest contribution to surgery by far that has been made in the nineteenth century.

I have in brief compass placed before you the great work that has been carried on for so many centuries in the locality in which we are met to-day, where you also for a few years are to do your work. The *genius loci* appeals to you as it has done to so many generations of scholars in the past. The old college left the classic neighbourhood of the cathedral: St. Mungo's College takes its place. Will the new college carry on the splendid traditions of enterprise and achievement with which its site is associated? That question the future alone can answer, but the answer will to some extent depend on you.

AN ANALYSIS OF  
TEN THOUSAND CASES OF DISEASE OR  
DISTURBANCE OF THE EYES, SEEN IN  
PRIVATE PRACTICE:

WITH NOTES AND COMMENTS.

By R. BRUDENELL CARTER, F.R.C.S. ENG.,  
OPHTHALMIC SURGEON TO ST. GEORGE'S HOSPITAL.

INTRODUCTORY.

I PURPOSE to bring to the notice of the profession something which may be called a statistical view of the private practice of an ophthalmic specialist in London, followed by such comments as groups of cases may suggest. Existing ophthalmic statistics, in so far as I am acquainted with them, have either been limited to particular diseases or have been derived from hospital sources; and in the latter case they bear very little resemblance to those which would be furnished by the work of a private practitioner. In his consulting room, cases which might be described as comparatively trivial will always be found in considerable numbers; partly, perhaps, because the wealthy classes are more sensitive to mere discomfort than the poor, partly because the occupations of the educated are more likely to produce such discomfort than those of the uneducated, and partly on account of greater leisure and better opportunities of seeking relief. I have for some years kept note-books with sufficient fulness to record all important particulars about my patients; and it occurred to me that by going back over these books until a sufficient number of cases had been reached it would be in my power to obtain considerable information on points concerning some of which I had only impressions, possibly not always correct. The number decided upon for this purpose

was 10,000, and it was an essential part of my scheme to include all the cases which had presented themselves, whether trivial or severe, without selection. Three classes only have been omitted—boys or young men who were brought to me because their parents wished to ascertain whether they were eligible, as far as sight was concerned, for some particular calling, as the army or navy, and whose eyes were perfectly healthy; patients who consulted me on account of headaches, supposed to be ocular, but for which I could not discover any ocular explanation; and a few, perhaps a hundred in all, about whom for any reason my notes did not contain sufficient information. With these exceptions, I have gone straight backwards through my books from April, 1891, until the required number was reached, and have included everything which has come before me. For the purposes of comment or illustration I shall feel at liberty sometimes to refer to cases treated during the last eighteen months, but none of these will be included in the actual numbers recorded.

Of the 10,000 persons from whom my figures have been derived, 4621 were males and 5379 were females. According to the census of 1891 the females in England and Wales are to the males nearly as 149 to 140; so that the proportion of females corresponding to 4621 males would be 4860. Apart, therefore, from the numbers of each sex in the population, there has been a distinct preponderance of women and girls among my patients; but this circumstance cannot be entirely attributed to any special proclivity on the part of the female sex to any single form of eye disease. There is, as I shall hereafter show, such a special proclivity in relation to senile cataract; but the figures which express it are not large enough to account for the whole of the feminine preponderance. I should be inclined to refer it to the greater sensitiveness of the female sex, to the more sedulous employment of their eyes over a variety of sedentary occupations, and to their weaker muscles, which are less able, as a rule, than those of men, to maintain prolonged efforts of accommodation or of convergence.

When the cases are classified according to the shape of the eyeball the various forms are found to bear the following proportions:—

	Males.	Females.	Total.
Emmetropia .. .. .	2123	2318	4441
Myopia, including simple and compound myopic astigmatism .. .	1464	1684	3148
Hypermetropia, including simple and compound hypermetropic astigmatism .. .	995	1328	2323
Mixed astigmatism .. .	39	49	88
Totals .. .	4621	5379	10,000

The cases of astigmatism amounted to 1412 (630 males and 782 females), of which 805 (369 males and 436 females) were of the myopic form; 519 (222 males and 297 females) of the hypermetropic form; and, as shown above, 88 (39 males and 49 females) were of mixed form. Among the last, mixed astigmatism, properly so called, was present in both eyes in 48 cases; in one eye, variously combined with other conditions of refraction in the other, in 30 cases; and the remaining 10 cases were not strictly mixed astigmatism, but presented nearly as many combinations of different forms, such as simple myopic astigmatism in one eye with compound hypermetropic astigmatism in the other, the details of which, in consideration of the smallness of the numbers, it would fulfil no useful purpose to specify.

In estimating the prevalence of disease among the 10,000 patients it must be remembered that the subjects of myopia, of hypermetropia, and of astigmatism, are often compelled to seek aid merely on account of the existence of these malformations, and of the difficulties which they place in the way of the continuous employment of the eyes; while the emmetropic persons, apart from disease, require aid on account of presbyopia only, for which, moreover, they are frequently content to use spectacles supplied to them by dealers. The cases of myopia and hypermetropia, on this account, present a smaller proportion of disease than the cases of emmetropia; and I find that 2347 cases of myopia and 1656 of hypermetropia are recorded as uncomplicated, while disease existed in 801 of the former and in 667 of the latter. The proportion borne by each form of disease to the total number of persons must therefore be reckoned upon a total of only 6000, or exactly 5997, instead of upon 10,000; but, on the other hand, a large number of patients will appear under more than one heading—as, for example, in the instance of one who was suffering from iritis or from episcleritis, and whose lenses presented indi-

ctions of commencing cataract. Some patients will even find place under more than two headings; so that the gross total will be made to appear larger than the number of persons from whom the figures were obtained. In classifying the observed conditions I have followed the table given by Cohn in Eulenburg's Encyclopædia; and, apart from the 4003 persons with simple myopia or hypermetropia, I have recorded—

Affections of the conjunctiva .. .. .	in 870 persons
"    "    cornea .. .. .	in 492 "

<b>Total .. .. .</b>	<b>7607</b>

The sum total of recorded affections, therefore (among which, although it is only a senile change, I have thought it convenient to include presbyopia), has amounted to 7607 in the 5997 persons; or, in other words, nearly 30 per cent. of these have admitted of being ranged under more than a single head. This percentage has been largely composed of the numerous cases in which presbyopia has existed in combination with commencing cataract, and of those, even more numerous, in which chronic congestion of the conjunctiva has been produced and maintained by other morbid conditions, or by the fatiguing efforts incidental to defective strength or tonicity of the ocular muscles.

In this and the following papers of the series I purpose to take the more important of the above-mentioned groups in succession and to illustrate such remarks as I may venture to make by the citation of any cases which appear to be of sufficient importance for the purpose.

**AFFECTIONS OF THE CONJUNCTIVA.**

The total number of affections of the conjunctiva amounted to 879, of which 437 occurred in males and 442 in females. The cases were as follows:—

	Males.	Females.	Total.
Acute (catarrhal conjunctivitis) .. .. .	82	47	129
Acute (purulent) conjunctivitis .. .. .	15	8	23
Chronic conjunctivitis .. .. .	272	323	595
Follicular granulations .. .. .	25	38	63
Gouty concretions .. .. .	4	3	7
Fatty growths .. .. .	18	15	33
Subconjunctival hemorrhage .. .. .	3	7	10
Conjunctival hypertrophy .. .. .	2	0	2
Dermoid or warty growths .. .. .	2	2	4
Pterygium .. .. .	0	2	2
Conjunctival cysts .. .. .	1	2	3
Epithelioma .. .. .	5	0	5
Nevoid patches .. .. .	1	0	1
Lacerated wound .. .. .	1	0	1
<b>Totals .. .. .</b>	<b>437</b>	<b>442</b>	<b>879</b>

The cases of acute (catarrhal) conjunctivitis were mostly of no great importance or severity, and included—besides those which were attributed, possibly for want of better knowledge, to cold or to atmospheric influences—some which were produced by the direct application of irritants. In several of these the irritant was a dense and sulphur-bearing London fog; in two it was chrysophanic acid, which had been applied as a remedy for some form of skin disease, and had accidentally found entrance into the conjunctival sac. Perhaps the point most worthy of notice in conjunctivitis is the very complete manner in which the use of nitrate of silver as a curative local application may be said to have been rehabilitated by the introduction of cocaine. Those who remember the Guthrie school of ophthalmic practice will remember that the nitrate, often in solutions or ointments of considerable strength, was regarded almost as a specific for many superficial ocular affections; and that it fell into comparative disuse chiefly on account of the pain attending its employment. By the use of cocaine, however, this objection may be completely removed; and I am accustomed, in all cases of acute, and in many cases of chronic, conjunctivitis of the catarrhal type, to apply cocaine first, generally in the form of a wafer containing the fiftieth of a grain, but sometimes by a drop or

two of a 10 per cent. solution; and, when this has had time to act—a time ranging from ten to twenty minutes—to paint the inflamed portions of the insensitive conjunctiva with a solution of nitrate—generally of five grains to the ounce, sometimes stronger—by means of a camel's-hair pencil barely moistened with it, so that it is only applied to the portions of membrane which the pencil actually touches. In cases of no great severity a single application of this kind, followed every four hours by the instillation of a drop of a solution containing two grains of cocaine and four of boric acid to the ounce of water, will generally be sufficient; but it will sometimes be necessary to repeat the nitrate daily or on alternate days for a short period of time. The use of the cocaine is not only attended by the advantage of rendering that of the nitrate painless, but it also limits the action of the latter to the parts actually touched by the brush. The absence of pain prevents lachrymation, and there is then nothing to cause the solution to be diffused over the conjunctiva or cornea. Even for adults the complete absence of pain is a strong recommendation of the method; but in children it renders the use of the nitrate absolutely unobjectionable, and thus restores to ophthalmologists what is, in my judgment, by very far the best and most efficacious of the so-called astringents.

The twenty-three cases of acute purulent conjunctivitis were mostly infantile. One of the exceptions was caused by accidental inoculation from an infant, and resulted in the loss of one eye of the patient, a young lady of twenty; while three cases were complications of diphtheria, all ending badly. I should perhaps include in this category a very remarkable instance in which I did not see the patient until long after the acute stage, and in which I was only consulted with reference to the propriety of endeavoring to reduce, by operation, the prominence of the staphylomatous cornea. The patient was the child of parents in good position, and the eyes were clearly described as having been quite healthy up to the age of fourteen days, when they became a little injected. It is therefore quite certain that the case was not one of ordinary ophthalmia neonatorum. The monthly nurse did not think the redness of the eyes sufficiently important to require the care of the doctor in attendance, and she proceeded to bathe them with milk, taking for the purpose a portion of the ordinary family supply. They speedily became intensely inflamed, with swollen lids and profuse discharge, and ultimately both corneæ perished. With our recent knowledge of the part played by milk in the diffusion of diphtheria I cannot but think it likely that in this case the milk was infected by the diphtheritic poison, perhaps not in sufficient intensity to affect any healthy persons who swallowed it, but in a way which produced the specific disease in conjunctivæ rendered vulnerable by the prior existence of slight catarrhal inflammation. It seems to me that the case affords a striking illustration of the dangers which may attend the use of milk; and that it should not be forgotten by those who undertake the duty of instructing midwives and nurses. In some of the midland counties of England the maternal urine was formerly a favourite domestic remedy for infantile purulent ophthalmia, and has no doubt been answerable for the destruction of hundreds of corneæ; but it requires only a little reflection to show that the use of milk, still a favourite application among ignorant people in many circumstances, may be fraught with many possibilities of danger.

The cases of infantile purulent ophthalmia were all seen in consultation when the disease was fully established, but they all terminated in complete recovery if seen while the corneæ were still bright. They were numerous enough to acquaint me with a very dangerous modern practice, that of treating such cases with solutions of perchloride of mercury, a plan which I do not hesitate to say is calculated to bring about the loss of many eyes which ought never to have been endangered. I believe it is adopted as the result of devout faith in three unproved hypotheses: first, that ophthalmia neonatorum is produced by the presence of certain bacteria in the conjunctiva; secondly, that to destroy these bacteria will be to cure the disease; thirdly, that perchloride of mercury is the best bactericide for the purpose. Clinical experience forbids me to accept the whole of these hypotheses. If the first and second be true, the third is certainly erroneous; and if the first and third be true, the second is at least doubtful. Before bacteria were ever heard of we knew how to cure ophthalmia neonatorum with absolute certainty, and the proper treatment is as efficacious now as it was then. My own first infor-

mation on the subject was derived from the "Lectures on the Principles and Practice of Physic" of the late Sir Thomas Watson, and I will quote from the first edition of these lectures, published in 1843. He says: "Purulent ophthalmia, as it occurs in newly born children, is a very common disease. It is very serious when neglected; it is very easily managed when it is seen and treated in time. . . . The disease may continue for eight or ten days without any affection of the transparent parts, and so long as these remain uninjured the eye is safe, provided that proper treatment be adopted." After an admirable description of the symptoms Sir Thomas Watson directs the use of a solution of four grains of alum in an ounce of water, and adds that the results of this method have been so entirely and uniformly satisfactory that he would never think of employing any other, although if the eye became insensitive to the stimulus of the alum a solution of nitrate of silver, of a strength ranging from one to four grains to the ounce, might be substituted with advantage. He also cites the experience at Moorfields of the late Sir William Lawrence as being absolutely in accordance with his own.

Forty years ago, when antiseptics were unknown in midwifery, and when the maternal secretions were scarcely suspected to be the ordinary cause of infantile ophthalmia, the disease was, as Sir Thomas Watson wrote, "very common," and it so befel that I had frequent opportunities of observing and of treating it. I thought it best to use a two-grain solution of nitrate of silver from the first, its action appearing to me to be more rapid, if not more certain, than that of the alum. The disease is now, fortunately, rare among the richer classes, but in the forty years I have no doubt seen many hundreds of cases, and I can most emphatically endorse Sir Thomas Watson's statement that the eye is safe as long as the cornea remains bright, provided that proper treatment be adopted. In the general term "proper treatment" I should include the effectual application of the silver or alum drops with sufficient frequency, at first usually every four hours, the purulent secretion being first removed by gentle irrigation with warm water and then the superfluous moisture absorbed by means of a soft rag. The edges of the lid should at the same time be prevented from adhering by the application of any simple ointment, and then the eyes will rapidly get well. I have not seen one single case in which the eye sustained injury when this treatment was adopted while the cornea was still bright; but I have seen several—comparatively lately—in which one or both corneæ had become cloudy, or had even ulcerated, under the use of a perchloride of mercury lotion, and I have not always been in time to prevent the occurrence of destructive mischief. It may be that nitrate of silver is a better bactericide than perchloride of mercury—I cannot tell; but of this at least I am certain, that the former will invariably cure infantile ophthalmia and that the latter will frequently fail to do so. Fortunately the habitual use of antiseptics in parturition has greatly diminished the frequency of the disease; but I can have no doubt that, if it were still as frequent as formerly, it would, under the treatment now too often practised, be far more destructive than it was when the precepts of Sir Thomas Watson were fresh in the recollection of practitioners.

I have lately seen a case which is perhaps worthy of being placed on record, and in which the appearances of purulent ophthalmia were curiously imitated. The patient was a little girl seven years of age, who was brought to me from the country on a certain Tuesday. The history was that on the previous Friday morning she was in her nursery playing with a sponge while she waited her turn for a bath. Something, it was supposed from the sponge, was said to have "squirted" into her left eye, which soon became painful, and the family medical man was sent for. He prescribed some lotion, probably containing cocaine, for it gave relief, which was speedy, but only temporary. On the next day the eye was worse, and the doctor is said to have everted the upper lid with some difficulty, but to have found nothing to explain the symptoms, which increased in severity day by day in spite of I know not what lotions and other treatment, the doctor himself not having made any communication to me. On the Tuesday morning I found the lids much swollen and a copious purulent discharge exuding from them. Partly on account of the swelling, and partly owing to the local tenderness and the fear and resistance of the patient, I was unable to see the cornea, so that I found it necessary to bring the child under the influence of chloroform. When this was done I lifted the upper lid and removed from beneath it a piece of

sponge of considerable size. The cornea was uninjured. As soon as the child recovered consciousness I said to her, "There was a piece of sponge in your eye." "Yes," she answered. "I put it there." This was her first confession, and none of the people about her had the least suspicion of the state of affairs. Some simple application was prescribed, and the conjunctiva speedily recovered from the irritation to which it had been subjected.

*Chronic conjunctivitis.*—The cases of chronic conjunctivitis—595 in number—include all those in which some surface irritation was associated with defective endurance of the ocular muscles, or with troubles arising from abnormal refraction or accommodation. Whenever under any of these conditions the patient is conscious of difficulties in working with the eyes it is very common to find the portion of the conjunctiva which lines the lower lid flushed and somewhat swollen, or studded with hypertrophied papillæ more or less numerous. The retro-tarsal folds often quite bulge out when the lower lid is drawn down and everted, and the veins which traverse the surface are often tortuous and distended. Gritty sensations will be described as consequences of even a very moderate use of the eyes upon any kind of near work, such as reading, or drawing or needlework, and there will be a general consciousness of the possession of the organs such as ought not to exist with regard to any part of the healthy human body. In these conditions it is common to find some demand for unusual or abnormal muscular effort in using the eyes over near occupations, and the people who suffer are usually those who write or read continuously, or who are engaged in other fine work, such as drawing or painting, which requires to be brought very near to the eyes. Often there will be need for spectacles, or those in use will be inadequate or in misfitting frames, which latter are fertile sources of discomfort. In such conditions we shall usually find that lotions alone are useless, and that better spectacles relieve without curing the conditions. It is usually necessary to combine both agencies: to place the eyes optically in the most favourable circumstances for their work, and then to use such astringents as occasion may require. In mild cases my first prescription is usually a drop of a solution of sulphate of zinc of the strength of two grains to the ounce, to be applied at bedtime, and a drop of a solution containing two grains of cocaine and four grains of boric acid to the ounce, to be applied twice a day, the lower lid being drawn down as completely as possible, so that either liquid has free access to the retro-tarsal fold. In cases of greater severity the application of a solution of nitrate of silver to the previously cocaineised conjunctiva, in the way already described under the heading "acute catarrhal conjunctivitis," will often expedite the cure, and may be repeated twice or thrice according to circumstances or to the severity or obstinacy of the case. And, as a rule, it may be safely said, in these conditions, that appropriate glasses will be insufficient without astringents, and that astringents will be useless without glasses.

As a pendant to the case in which acute conjunctivitis was produced by the presence of a piece of sponge, I may mention one of a chronic character which was brought to me as having resisted treatment. On everting the upper lid of the affected eye I had the good fortune to obtain a glimpse of some foreign body, high up under the retro-tarsal fold, and presently succeeded in removing an end of sewing cotton rather more than half an inch in length, which was occupying a horizontal position quite above the cornea. The patient was a young lady, from whom no admissions were to be obtained, but, some months later, she returned in a similar condition and another piece of cotton was removed. In a general way foreign bodies in the conjunctival sac, especially when in their most common position, just above and within the margin of the upper lid, act chiefly by the irritation of the corneal surface. The effects which they produce will be best considered when the affections of the cornea come under review.

*Follicular granulations.*—In the chronic cases last referred to it is not uncommon to hear the somewhat hypertrophied papillæ of the lid linings described as "granulations," but such an employment of the word is very misleading; it should be reserved for a much less common condition, of which, as will be seen from the figures given above, only fifty-eight examples came before me among the ten thousand patients. In these the retro-tarsal folds, especially those of the lower lids, were studded with semi-transparent lumps, which have been likened by imaginative people to boiled sago grains. These lumps are strictly analo-

gous to enlarged lymph glands ; and in some persons they give rise to great irritation. They are extremely intractable to astringent applications, and to destroy them with any kind of caustic leaves a hard cicatrix which may in itself be an abiding cause of trouble. For several years it has been my practice to crush them with forceps as a means of causing them to be absorbed, but quite lately I have been made acquainted with a still better method devised by Dr. Knapp—that of squeezing them between roller forceps, by which means the whole of the contained substance is forced out without any appreciable solution of continuity of the conjunctiva, and the subconjunctival tissue is completely freed from the morbid material. The operation, although short, is painful, and the patient should be brought under chloroform or ether. A large fold of the affected conjunctiva is pinched up with ordinary forceps and then grasped between the blades of the special forceps, which are made to compress it firmly as they are drawn off. A quantity of pulpy matter and blood is pressed out, and the proceeding must be repeated until every affected portion of the membrane has been emptied of the growths. The lids will be a little tender for a day or two, but even from the first the relief to the patient is considerable, and I have not yet seen any reproduction of the material. The special forceps terminate in portions which may be compared to stirrup irons, and the cross-piece corresponding to that on which the foot rests in a stirrup is a steel cylinder which revolves freely upon an axis. The most convenient length for this cylinder is about half an inch, and it is essential that the instrument as a whole should be strongly made and capable of subjecting the tissues which it holds to firm pressure.

*Gouty concretions* of the conjunctiva form an affection about which there is little to be said. They appear to be composed of the same material as ordinary chalkstones, and can be easily turned out of the tissues by the point of a cutting needle or cataract knife, cocaine being first applied. As a rule, however, they are well covered by the conjunctival epithelium, and produce less irritation than their appearance would at first lead one to expect.

*Fatty growths* of the conjunctiva are only an exaggeration of a normal condition. In nearly all persons, as middle age is reached, a slight deposit of fat may be observed among the interstices of the subconjunctival tissue ; and this deposit, when it is formed in more than usual quantity, becomes forced into the horizontal line by the pressure and closure of the lids, and often projects in the form of a little yellow prominence on either side of the cornea. These prominences are absolutely harmless and unimportant, but I have seen them attain such magnitude as to become pedunculated where they were nipped between the lids. Moreover, they are often attended by an increased development of the conjunctival vessels ; and partly on this account and partly owing to their colour and occasional prominence they may easily become somewhat unsightly. If their removal is desirable for cosmetic reasons, they may be pinched up with ordinary fixation forceps, and cut off with scissors, cocaine being first applied. The conjunctiva should then be undermined along the upper and lower edges of the wound, and these drawn together by one or two threads of very fine suture, which may be removed on the following day. When the vascularity which immediately follows the healing has subsided, the cicatrix will be invisible, and it will at the same time produce so close a union between the conjunctiva and the sclera that no fresh accumulation of fat is to be looked for.

*Subconjunctival hæmorrhage*, apart from the causes from which it occurs, may be regarded as a trivial affection. A small vessel may easily be ruptured by a slight blow or by severe coughing, or by the straining of parturition. When no manifest cause of the rupture is discoverable it may be of somewhat grave significance. In advancing life it may point to brittleness of the bloodvessels generally, and may be the precursor of intra-cranial hæmorrhage ; and in youth I have twice seen it produced by nocturnal and previously unsuspected epilepsy. Looked at as an isolated occurrence it is unimportant. The effused blood will be quickly absorbed, and although the feelings of the patient will usually be soothed by the application of a lotion, I have no reason to believe that absorption will be thereby promoted.

The remaining conjunctival affections, which, as the figures will show, are comparatively seldom met with, do not appear to call for any special remark, either as regards causation or treatment.

(To be continued.)

## A MODIFICATION OF THE OPERATION FOR THE DIVISION OF THE SUPERIOR MAXILLARY NERVE.

By RUPERT C. CHICKEN, F.R.C.S. ENG.,  
SURGEON TO THE NOTTINGHAM GENERAL HOSPITAL.

ALTHOUGH the methods of operation that have been devised for neurectomy of the second division of the fifth are numerous, I fail to find one which seems to me free from one or more of the following essential conditions to be fulfilled in order to constitute an operation which, at the same time that it gives the operator a clear view of the structure he is seeking, entails the least possible structural damage and disfigurement to the patient with the most complete relief from his symptoms. (1) A well exposed situation for incision ; (2) non-implication of important structures or organs, such as the orbit or eyeball ; (3) good anatomical landmarks ; (4) avoidance of bleeding or oozing ; (5) free access to the nerve trunk ; (6) practicability of removal close to the foramen rotundum ; (7) the least possible disfigurement or loss of function afterwards. The first and seventh of these conditions limit the choice of the seat of operation to either the cheek or zygomatic fossa, but the performance of the operation through the infra-orbital foramen and canal is in opposition to the second, third, fourth, fifth and sixth ; whereas a carefully planned opera-

A, Zygoma. B, Masseter. C, Temporal. D, Posterior surface of superior maxilla. E, Pterygoid. F, Superior maxillary nerve.

tion through the zygomatic fossa fulfils all the conditions. In the operation through the antrum the oozing is very free, and the area of operation necessarily so extremely limited, especially at the far end of the funnel-shaped tunnel made by the trephine, that the view of the parts sought for is most imperfect and obscure. In the operation about to be described through the zygomatic fossa there is practically no bleeding, but there is plenty of room for work and a good view of the nerve in its course from the foramen rotundum to the infra-orbital canal, and the whole of that portion of the nerve lying between these two points can be readily excised.

In April of this year H. W—, aged fifty-six, was transferred to my care at the Nottingham General Hospital suffering from severe and sudden seizures of neuralgia. He had been subject to the attacks for about seven years, and in this period every conceivable form of treatment, including the

extraction of all his teeth, had been adopted without any benefit. His attacks of pain commenced quite suddenly in the region of the right upper canine, gradually extending over an increasing area until the whole of the second division was involved. The paroxysm having lasted a minute or more, as suddenly left him. He had many attacks in the twenty-four hours. He earnestly asked for relief by operation. On April 26th a vertical incision was made over the broad base of the zygomatic process of the malar bone about two inches long; another parallel to this over the zygoma, just in front of the temporo-maxillary articulation. These were joined about an inch above the zygoma by a horizontal incision and the flap reflected downwards. The temporal fascia was now divided along the border of the zygoma and the bone sawn through as close as possible to the frontal process of the malar bone anteriorly and the temporo-maxillary articulation posteriorly. This fragment was turned down with the attached masseter. A director was passed under the temporal muscle, its fibres divided close to the coronoid process, and the belly of the muscle turned up with the temporal fascia. The fat filling in the temporal fossa, the pterygoid muscles and the internal maxillary artery were exposed. With a slender blunt raspatory a dissection was made along the posterior surface of the superior maxilla until the prominent spine at the corner of the pterygoid ridge was distinctly felt by the left finger. Internal to this the superior maxillary nerve running from the foramen rotundum to the infra-orbital foramen was easily caught on a strabismus hook. The nerve was now drawn upon anteriorly and divided as close as possible to the foramen rotundum. Traction was made posteriorly and the nerve again divided close up to the infra-orbital foramen and removed. There was no bleeding and the various structures were clearly visible. The deep temporal artery was tied in two places and divided, as it lay exposed in the wound, as a precautionary measure; but I cannot say that it was absolutely necessary. The parts were now replaced and a drainage-tube inserted. The zygoma was wired at each end with silver and the flap of skin replaced. The patient made an excellent recovery and has been entirely free from pain since. He has a firm zygomatic arch and can bite as hard and as firmly as ever. There is no disfigurement except the slight scar. He can use well his temporal and masseter muscles. The chief points to be observed in the performance of this operation are: (1) The division of the zygoma as anteriorly as possible, the masseter to be left attached to the zygoma; (2) the division of the temporal muscle instead of the coronoid process of the jaw; (3) the subsequent use only of blunt instruments in separating the tissues. By these means hemorrhage is prevented and the various steps of the operation clearly seen.

Nottingham.

#### METROPOLITAN HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF THE SKULL;  
TREPHINING; REPLANTATION OF BONE; COMPLETE  
CLOSURE OF THE WOUND; RECOVERY.

(Under the care of Mr. WALSHAM.)

IN THE LANCET of May 28th, 1892, reported by Dr. C. F. Marshall, the then senior house surgeon, we published a case of compound depressed fracture with replantation of bone, and immediate and complete closure of the wound, that had recently been under the care of Mr. Walsham in the Metropolitan Hospital. The present is an almost identical case, differing only in that the child was a year older and that the trephine had to be applied before the depressed bone could be raised. In this as in the former case the edges of the wound were refreshed before the sutures were inserted, the wound was accurately closed without the employment of any drain and the

fragments of bone that had been removed replaced. At the first dressing the wound was found to have healed by the first intention. In some editorial remarks on the former case special attention was drawn to the entire closure of the wound at the completion of the operation without employment of a drain. "This case of compound depressed fracture," we said, "offers a very great contrast as regards treatment to the method of procedure which is usually practised for these injuries, and it is obvious from the description that the number of patients in whom it can be carried out with safety is a limited one." It is obvious that it belongs to a different group from the others mentioned in Mr. Walsham's remarks, for, as we pointed out in the former case, the infliction of the wound is in no way under the control of the surgeon in the compound fracture, and there is a great possibility that it is already infected beyond hope of remedy. It is interesting to note that this case resembles some others which were brought before the Medical Society last session by Mr. J. H. Morgan and Mr. W. H. Battle, in that the patients were children and the bone was healthy and vascular. We are indebted for the notes of the case to Mr. Fraser, senior house surgeon.

C. H.—, a girl of nine, was admitted to the Metropolitan Hospital at 11 P.M., June 4th, 1892, with a compound depressed fracture of the vault of the skull caused by a blow with the iron bar of a swing. The wound was about two inches long and situated over the right upper frontal region. The scalp was much bruised and the skin ingrained with dirt. At the bottom of the wound the bone was felt depressed about half an inch below the surface of the skull over a circular area the size of a halfpenny. There were no cerebral symptoms. The wound was temporarily cleansed and dressed. On Mr. Walsham's arrival at the hospital the scalp was shaved for five inches around the wound, washed and scrubbed with soap and water and a stiff brush, all grease removed with turpentine, again washed with clean water, and finally with perchloride of mercury (1 in 2000). The wound itself was next carefully cleansed, all hair that had escaped in shaving the scalp removed, and ragged and dirt-ingrained portions of tissue carefully excised. The wound was then prolonged, a flap of the scalp turned up and protected, and as the depressed bone could not be raised a medium-sized trephine was applied over the outer edge of the depression and the depressed fragments removed. These were placed in hot perchloride solution (1 in 4000). The dura mater was not injured. The fragments of bone were next replaced with their smooth surfaces towards the dura mater, but the periosteum could not be brought over them, a large piece having been torn away. The bruised edges of the scalp having been cut off all round the wound, the flaps were brought accurately together with silk sutures. No drain was employed. The wound was dressed with moist sal alembroth gauze and wool, and firm pressure applied over the whole vault of the skull. The child was given ten grains of calomel at once and kept on slop diet for a week; she had no bad symptoms. On June 13th the wound was dressed for the first time and found completely healed by the first intention. A fluctuating swelling was felt beneath the scalp over the situation of the wound, but was not touched. On the 16th the wound was again drained and the stitches removed. On July 18th the child was discharged; the fluid swelling had completely disappeared and the skull at the seat of fracture was firmly consolidated. She was kept under observation in the hospital for over a month, but she was practically well at the end of ten days from the injury.

*Remarks by Mr. WALSHAM.*—This makes the sixth case recently under my charge in which I have completely closed the wound without drain after operation on the skull. In all, union by the first intention has practically been the result. In two of the cases (those at present under review) the operation consisted in the removal of depressed and loose fragments of the cranium. In three the operation was that of craniectomy, and in the remaining case trephining for loss of memory. With the exception of the last case, a man aged thirty, the patients were children. In the craniectomies and the case of trephining for loss of memory the bone was of course not replaced. Thus there is a series of six consecutive operations on five patients (one of the craniectomies having had a strip five or six inches long removed at an interval of a month from either side of the head) in which success attended the complete closure of the wound. To attain this end the greatest care and attention to detail are no doubt necessary. In the first-

place, it is obvious the wound must be rendered absolutely aseptic. Thus in both the cases of compound fracture the scalp was shaved for at least five inches around the wound. It was then washed with soap and water and scrubbed with a brush, next washed with turpentine, and then with perchloride of mercury solution (1 in 500). When the toilet of the scalp was completed the wound next received attention; the edges were especially looked to; any short hairs that had escaped when shaving the scalp were removed, all dirt was scrupulously washed away, loose tags of bruised and lacerated tissue cut off close with curved scissors and the dirt-ingrained tissue dissected off. Finally, the skull was irrigated with perchloride lotion (1 in 2000). All this of course takes time; indeed, fully three-quarters of an hour was thus spent before beginning the operation; but the time was saved in the end, for nothing further, after the wound was once closed, was called for till it had healed. Perhaps one of the most important points to ensure immediate union is to completely cut away the edges of the original wound in the scalp, and this is best done last thing before applying the sutures, as then no further injury of the soft tissues is received by the use of retractors or forceps or by handling. Indeed, all injury of this kind should be carefully avoided by enlarging the original wound considerably, turning back large flaps of the scalp and protecting them whilst thus reflected by soft, moist compresses of warm lint so arranged as, when once placed in position, to allow free room for manipulation on the bone; the edges need not be again touched till the operation is complete. Any wound of the dura mater should be closed by fine aseptic silk sutures, so as to cut off as quickly as possible communication between the subdural space and the wound. It appears probable that when the serous surfaces of the dura mater are brought into contact healing occurs as rapidly as in the case of the peritoneum. Sufficient bone should be replaced to completely fill the wound, picking out such portions as have the smooth surface of the inner table intact to place in contact with the dura mater. By clipping the pieces with bone scissors they can be made the better to fill up inequalities; and it would seem an advantage when two portions have to overlap that the opposing surfaces should consist of exposed diploë. One would argue from analogy that the replaced bone would be more likely to retain its vitality and new bone be more likely to be formed to fill up the interstices in the replaced bone, when the pericranium can be brought over it. But that a covering of pericranium is not absolutely necessary is well exemplified by these two cases, since in both so much pericranium was torn away that the replaced bone could not be thus covered. It has been advised that when the wound is accurately closed after the operation of trephining &c. if any fluid collection is felt beneath the scalp a probe should be introduced under some of the stitches to let it escape. This is quite unnecessary, and further I think exposes the patient to a risk of septic trouble. Our aim, I hold, should be to get the edges to unite throughout by primary union and thus render the wound subcutaneous as soon as possible. Then if we have ensured the wound being aseptic to start with, any danger of secondary infection is, one might almost say, completely avoided. The fluid, if left alone, is slowly absorbed. I have seen so much fluid collect beneath the closed wound that a distinctly raised and freely fluctuating swelling was produced, but so evenly and completely have the edges of the wound united that not a drop of fluid escaped on fairly firm pressure being made over the fluctuating swelling and complete absorption occurred without rise of temperature. On the other hand, where a probe has been introduced to let the fluid out, I have known it continue to escape for some weeks. Where there has been no wound of the dura mater the fluid, I take it, is merely the serous exudation from the surfaces of the wound, but in other instances, especially where it has continued for some weeks, through some slight, though possibly at times imperceptible, lesion of the dura mater from the subdural space.

### SUNDERLAND INFIRMARY.

#### TWO CASES OF VAGINAL HYSTERECTOMY FOR CANCER; RECOVERY.

(Under the care of Dr. JAMES MURPHY.)

WHEN this operation was first introduced to the notice of the profession it did not yield good results, but as the technique has become more perfected the recoveries have

been much more numerous, and it is viewed with considerable favour at the present day. Much has been written on the subject during the last year or two, until the literature is extensive, and the greater part of the testimony of the various writers is in favour of this operation for cancer of the uterus, when it appears possible to remove all the disease by it, and of its performance as soon as possible after the disease is recognised. Martin<sup>1</sup> thinks the operation should not have a mortality of more than 5 per cent. Leisse gives the statistics in eighty cases which had been operated on by him over two years previously. Of these, 56.25 per cent. were living, and 43.75 per cent. died. Of the 35 deaths 8 died of other affections. Of 70 cases operated on by Schauta 5 died (2 as a result of the operation).

On July 13th, 1891, Mrs. W—, aged forty-seven, was sent into Dr. Murphy's wards for vaginal hysterectomy on account of malignant disease of the cervix from which she had suffered for several months. The disease was limited to the cervix, which was fairly long; the vagina and glands were not involved. The uterus was freely movable and could be pulled down as far as the perineum. For four days carbolic injections were administered three times daily and on the 17th hysterectomy was performed. She was placed in the lithotomy position and secured by Clover's instrument. The cervix was seized by Péan's large vulsellum and pulled down; the mucous membrane was cut through well above the diseased part with scissors curved on the flat both posteriorly and anteriorly; the bladder and rectum were carefully detached, partly by scissors but chiefly by the fingers, and the peritoneum before and behind was torn through. Greig Smith's clamps were applied and the uterus removed by his knives. No vessel required ligature; the clamps were left on for forty-eight hours; boracic acid injections were carefully used twice daily. There was no rise of temperature and no constitutional disturbance, and she left the hospital in a month quite well. It is reported that she continues quite well, and so far there is no sign of recurrence of the disease.

On May 2nd, 1892, Dr. Bernard of Silksworth sent in Mrs. D—, aged forty-two, in a similar condition; except that the cervix was very short and the mucous membrane had to be stripped off before the uterus could be grasped by the vulsellum; in other respects the operation and the result were the same.

*Remarks* by Dr. J. MURPHY.—Operations for malignant disease of the uterus, as operations for malignant disease elsewhere, are very unsatisfactory as regards the prospects of absolute cure, or of any great prolongation of life, yet life may be somewhat prolonged and made very much more comfortable by free scraping with Volkman's spoons in cases unsuitable for hysterectomy, but where the disease is confined to the cervix and the uterus movable, the operation of hysterectomy presents great advantages. It is not particularly difficult or dangerous in suitable cases, still it is not even yet as frequently resorted to by English surgeons as by our Continental and Transatlantic *confrères*. Vaginal hysterectomy is much safer than hysterectomy by abdominal section. Whether some form of clamp or by ligature is the best means of securing the broad ligaments is still an open question. It is both unnecessary and dangerous to completely retrovert the uterus, as was formerly done in securing the broad ligaments.

<sup>1</sup> Sajous, 1892, vol. II., f. 22.

THE TRUSS SOCIETY, LONDON.—On Tuesday last, at a meeting of the governors of the City of London Truss Society, it was unanimously agreed that sufficient stocks be sold out to produce £3000 in order that the committee might be enabled to provide new buildings for the better accommodation of the increasing number of patients, to pay off a recent loan, and generally to meet the increased requirements of the Charity.

ROYAL COLLEGE OF SURGEONS IN IRELAND: SCHOOLS OF SURGERY.—On Tuesday next, November 1st, at 12 o'clock, Mr. Hamilton, President of the College, will present the prizes awarded to the successful students of the previous sessions 1891-92. The prizes annually awarded in the schools of surgery consist of gold, silver and bronze medals, the Barker Anatomical Prize of £21, the Carmichael Scholarship of £15, the Mayne Scholarship of £15, the Stoney Memorial Prize, together with other money prizes amounting to about £100. On the same occasion the schools will be opened for the winter session 1892-93, when lectures will commence.

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

#### *Amputation for Diabetic Gangrene.*

THE first ordinary meeting of this Society for the present session was held on Oct. 25th, the President, Sir Andrew Clark, in the chair.

Mr. R. J. GODLEE read a paper on Amputation for Diabetic Gangrene. He said that his excuse for bringing some rather ordinary cases before the Society was that the term "diabetic gangrene" was made to include several different conditions now beginning to be recognised, and also that modern surgical improvements had modified our views with regard to amputation for this disease. Diabetics were more liable to gangrene, when once started, than others for several reasons, but the determining causes were the same as in other forms of gangrene. These were inflammatory conditions, including carbuncles, noma vulvæ, and rapidly spreading ulcers of the legs, as well as extensive sloughing of septic wounds; atheroma of vessels and peripheral neuritis, which was now generally recognised as being caused by glycosuria, and as giving rise to many neuralgic and other symptoms. The object of the paper was to point out that the so-called diabetic gangrene in most cases depended on one or other of these conditions. If the former, progress of the disease was rapid and the pain was great; if the latter, the pain was insignificant or absent and the progress slow. The former must be treated by amputation at or above the knee, because it had been shown that in these cases the degeneration almost always reached the knee, but very often did not extend further; the latter might either be left alone or treated by amputation close to the necrosed part. The following cases were illustrations of these facts. 1. A man of forty-eight, who had partaken freely of alcohol for many years. Gangrene started from a sore by the nail, and proceeded rapidly on to the dorsum of the foot. A circular amputation was done above the knee, and the patient made a good recovery. The vessels from the part removed were shown, and it was seen that the degenerative changes were very far advanced and extended as high as the popliteal artery. Microscopical sections of the vessels were also shown. The patient was present. 2. A man aged sixty-one had gangrene of the little toe caused by a corn. A line of demarcation formed and amputation was done through the dusky tissues close above the spiculated part. The wound was left quite open and the patient made a good recovery. 3. A lady, aged seventy-three, had gangrene of one toe, not very painful, and starting from a suppurating corn. The toe separated and the wounds healed after several incisions had been made in the sole and on the dorsum of the foot.

The PRESIDENT suggested that perhaps the exceeding dryness of the tissues might act as a probable cause both of the gangrene and of the neuritis.

Mr. HUTCHINSON referred to a paper which he had read before that Society some time ago on amputation above the knee in cases of senile gangrene, and in one of the cases which he instanced there was sugar in the urine. In discussing this subject it should be remembered that there were cases of diabetes and diabetes, and that many cases in elderly people with sugar in the urine were not at all acute. He had done many operations—certainly many cataract operations—in young people with diabetes, and he had not been accustomed to regard the presence of the latter disease as adding much to the risk. All his experience since the writing of his paper had confirmed him in the idea that operation above the knee was the right procedure.

Mr. GOLDING-BIRD, referring to Mr. Godlee's recommendation to amputate low down in cases due to neuritis, wished to relate a case which bore upon that point. A patient suffering from locomotor ataxy came under his care; Mr. Durham had previously removed a toe and the adjacent part of the foot for perforating ulcer. Two fresh ulcers had formed under the ball of the foot. A Syme's amputation was performed after failure of repeated endeavours to get the sores to heal. The amputation was done low down, because the disease was due to a neuritis and not to a disease of the vessels. The man did well, and the wound healed up. Later an ulcer reappeared on the stump, but the surface was

liberally destroyed with nitric acid, and it was scraped, with a good result.

Mr. SPENCER said that the paper which he communicated to the Society at its last meeting covered much the same ground as that of the author, and the conclusions arrived at were the same. He related a case to illustrate the value of amputation where an inflammatory lesion was present.

Mr. CRIPPS said that he found that some time ago cases of senile and diabetic gangrene were commonly classed together and the older surgeons condemned amputation in either variety. The treatment had since been completely changed by the introduction of the antiseptic system and the more accurate knowledge that had been acquired of the manner of treating wounds. He thought that with antiseptic measures it would not be necessary to amputate so high up as the knee.

Mr. SHEILD referred to four cases of whitlow which he had seen and which he thought had an important bearing on some of the remarks which had been made. If an elderly person without an accident developed a severe whitlow of the finger, sugar would be found in the urine. They usually sloughed and sometimes ended fatally. In one case in which the finger was amputated the digital arteries were secured with great difficulty and the patient died from a spreading of the gangrene to the hand and wrist. In another case of gangrene of the finger after amputation a large slough formed on the dorsum of the foot, which afterwards separated, and the ulcer healed soundly. This class of case occurred in elderly people who were glycosuric rather than in young diabetics. In a certain number of cases of diabetes he had observed an acute extensive necrosis of the mastoid as a complication.

Mr. TREVES thought that the paper would go far to upset what had been regarded as a surgical constant. His experience in the matter of operation in diabetic gangrene was short and decisive. He did the high amputation in two cases, and in both the patients died with what he could only term a reckless rapidity; he had declined similar operations since. There seemed to be a time in the affairs of diabetes when operations could be carried out with safety, but at other periods of the disease they were fraught with danger.

Dr. DAWTREY DREWITT said that the gist of the debate seemed to emphasise the fact that every small scratch or blister in a case of diabetes ought to be treated antiseptically.

Mr. RIVINGTON said that evidently no hard-and-fast rule could be laid down with regard to the treatment of diabetes, but every case should be judged on its merits. He had had one or two cases which bore out the value of Mr. Hutchinson's method. In cases in which the gangrene was affecting the constitutional condition of the patient it was only fair to give a chance of recovery by amputation. With regard to frost-bite gangrene, some advocated leaving all cases alone, but that rule he had departed from with advantage.

Mr. GOULD related the case of a man forty-nine years of age who for five years had suffered from diabetes. In February last he sustained a trifling injury to the left foot and the wound did not heal. In July there was gangrene and spreading suppuration reaching up as far as the middle of the leg. Free incisions had been made, opium administered and a moderate restriction of diet enjoined, but this did not affect the excretion of sugar. He then amputated at the knee-joint by Stephen Smith's method, using antiseptic precautions. Within three days the sugar was nearly gone, and within nine days it had entirely disappeared. The wound healed well, and at the present time there was a trace of sugar in the urine.

Dr. GEORGE HARLEY remarked that in many cases of diabetes in which the patient was seized with a severe intercurrent malady the sugar entirely disappeared, and remained absent until convalescence began to be established.

The PRESIDENT corroborated this observation, and said that in cases of enteric fever in diabetes, as soon as the fever had fairly set in the sugar disappeared and remained absent till convalescence.

Mr. GODLEE, in reply, said that so little was known of the reaction of tissues to micro-organisms that he purposely avoided discussion of the influence of dryness &c. on the progress of the lesions. In one of his cases the diseased condition of the vessels demonstrated the futility of amputation low down. It certainly was not safe to amputate, or, indeed, to operate in all cases of diabetes. He had heard it stated that even so slight a thing as a more strenuous modification of the diet had produced a fatal result in some cases; and

this was worth bearing in mind, because in some of the fatal cases the patients might probably have died, not of the amputation but from the highly scientific diet to which they were subjected.

### MEDICAL SOCIETY OF LONDON.

*Traumatic Volvulus of Small Intestine treated by Abdominal Section.—The Treatment of the Peritoneum in Abdominal Surgery.*

An ordinary meeting of this Society was held on Oct. 23rd, the Vice-President, Dr. Symes Thompson, in the chair.

Mr. G. R. TURNER read a paper on a case of Traumatic Volvulus of the Small Intestine which was treated by abdominal section. The patient, a boy aged seven, was admitted to the Seamen's Hospital on July 26th, 1891, having fallen from a height of twelve feet against the pole of a boat and then into the river mud. He was much collapsed and vomited several times. He soon became restless, with abdominal pain and tenderness referred chiefly to the right iliac fossa. The vomiting continued and acquired a faecal odour. Mr. Turner was sent for, and some twenty-four hours after the accident he opened the abdominal cavity. There was no evidence of any rupture of the intestine and no general peritonitis. A mass of entangled intestines (ileum) was felt to the left of the middle line. This was easily unravelled. On examining the intestine two collapsed, flattened parts, one foot and two feet in length, and separated from each other by about four feet of intervening intestine, were discovered. The collapsed gut at either end passed abruptly into the neighbouring intestine. There was no tear or rent found in either mesentery or omentum and no band of any kind was discovered. There was no further vomiting after the operation. Flatus was passed on the second day and the bowels acted naturally on the eighth day. The patient made an uninterrupted recovery. Mr. Turner made some remarks on the diagnosis, and suggested that the volvulus was caused by the fall, as the boy was previously perfectly well. The success of the operation was attributed to its early performance before abdominal distension or intestinal adhesion was present.—Mr. SHEILD remarked that these cases were excessively rarely met with in practice. When grave intestinal symptoms appeared, so to speak, spontaneously without obvious traumatism, there were still many who doubted the propriety of immediate operative interference; but in a case such as that related, where the symptoms developed immediately after an injury, he thought that most surgeons would at once perform laparotomy.—Dr. FRANCOIS HAWKINS said that when fifteen years ago he was a pupil at a county hospital he remembered seeing a female admitted, between thirty and forty years of age, who had fallen from a chair and sustained an abdominal injury. She died with symptoms of acute intestinal obstruction, and at the necropsy, when the abdomen was opened, there was found a figure-of-eight twist of the intestine at the level of the umbilicus which became easily unravelled on removal of the pressure of the abdominal wall.—Mr. JESSERT referred to some experiments which were brought before the Congress at Berlin some time ago, in which a loop of intestine was cut off from the main channel and both its ends were closed with suture. The continuity of the main channel of the bowel was then restored by uniting the upper and lower cut ends. In a few days it was found that the portion of intestine which had been closed gave rise to obstructive symptoms, owing to its becoming distended with its own secretion. He had repeated this experiment on a dog and confirmed the observation. He detached a piece of small intestine sixteen inches in length, washed it well out with carbolic solution, and then closed both ends of the loop, of course leaving the mesenteric attachment intact. He then re-established the continuity of the main bowel with a circular suture and the dog recovered from the operation. Twelve days later the animal was killed and the closed loop was found filled with fluid; six ounces of this were collected and analysed; it contained leucocytes and fat and was evidently succus entericus. If, therefore, one had to deal with a volvulus, which on exposure was found to constrict the gut above and below at the twist, and which could not owing to adhesions be untwisted, and if it were decided to short-circuit the intestine by means of Senn's plates and leave the volvulus with closed ends, it would be necessary, owing to this secretion, to provide for the drainage of the closed loop by anastomosing it with a neighbouring coil of intestine. The cases requiring this were of course very rare.—Mr. STABLEY re-

lated a case which had happened in the practice of Dr. Nicoll of Margate, who was called to see a child five years of age which while playing had struck its abdomen against a seat. When he saw the girl a short time afterwards there was no shock, but some colic, a little tenderness to the left of the umbilicus and vomiting of undigested food. The next day there was no action of the bowels and no tenesmus, though the vomiting continued. Twenty-four hours after the onset of the symptoms the child died, and at the necropsy a volvulus of the small intestine was found thirty inches from the pylorus; there was no abnormality in the length of the mesentery.—Mr. CRIPPS advocated a long incision in cases of exploratory laparotomy. Surgeons too often made a short incision, and were then much hampered in their inspection of the gut. The intestines should be allowed to crowd out of the wound and be received on a warm damp cloth. If there were much difficulty in returning them a puncture should be made, the contents evacuated, the incision closed and the gut would then readily return.—Mr. TURNER, in reply, said that the case related by Dr. Hawkins bore out some experiments which had been made as to volvulus; that it could be easily produced when there was some obstacle in front like the anterior abdominal wall, but when the resistance of the latter was removed it just as easily unravelled. In a case which he operated on, which was moribund where the obstruction had been unrelieved for six days, it was found at the operation that the volvulus was nevertheless quite easily unravelled. The patient, however, died from shock. He preferred a long incision in these cases; he found first the end of the ileum near the caecum, and traced the small intestine from below upwards till he arrived at the obstruction.

Mr. MEREDITH read a paper on the Treatment of the Peritoneum in Abdominal Surgery. We reserve an account of this paper for our next issue.—Mr. DORAN said that the substance of the paper was insistence on avoiding unnecessary injury to the peritoneum. It was impossible to determine what amount of necessary injury the peritoneum would tolerate, and it was quite impossible to distinguish between the harm done to the peritoneum itself and that arising from cold or handling. He asked Mr. Meredith if he thought that accumulations of flatus could bring on peritonitis. He was certain that manipulation of the peritoneum had in certain cases a salutary effect.—Mr. SHEILD remarked on the difficulty in some cases of preventing the peritoneum from being stripped up from off the anterior abdominal wall, and to prevent this he usually stitched it provisionally to the skin before proceeding to manipulate the abdominal cavity.—Mr. MALCOLM said that it was essential after the operation to maintain a clear intestine. The great majority of the fatal cases died from septic peritonitis or from obstruction to the bowels. The modern plan was to adopt starvation as to food by mouth in order to rest the intestine and to give far less opium than was formerly the case.—Dr. SYMES THOMPSON said that since the introduction of antiseptics much better results had been obtained in operations on the pleura and lung at Brompton.—Mr. MEREDITH, in reply, said that he still believed thoroughly in antiseptics as used by Lister, with the exception of the spray, his reasons for abandoning which he had stated fully in the paper. Stripping off the peritoneum from the anterior abdominal wall might occur where one had to deal with a thick cyst wall firmly adherent to the serous membrane; in such cases it was important to allow no blood to remain between the peritoneum and the muscle sheath. His great point was that the peritoneum should be left as much as possible in the normal state; avoiding rough manipulations and flushing without sponging was the best means for securing this. In cases of tubercular peritonitis, on the contrary, rough sponging was wanted over the affected surface.

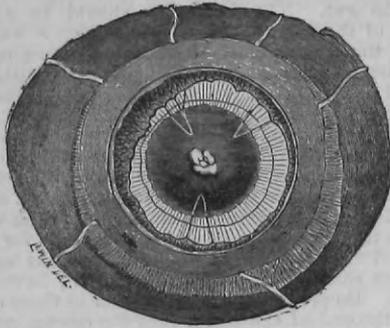

### OPHTHALMOLOGICAL SOCIETY.

*Congenital Defects of the Iris and Glaucoma.—Neuro-retinitis following Influenza.—Optical Condition of Fifty Persons complaining of no Ocular Disturbance.*

THE first ordinary meeting of the session was held on Thursday, Oct. 20th, the President, Mr. H. Power, in the chair.

Mr. TREACHER COLLINS gave a lantern-slide demonstration of the microscopical characters of three eyes—(1) Congenital absence of the iris and opacities in the lens; (2) congenital

coloboma of the iris and lens outwards, with glaucoma; and (3) traumatic aniridia and glaucoma. In the first case he found that the ciliary body ended in a rudimentary iris in its entire circumference, though clinically none could be seen. On one side of the sections a small piece of the sphincter muscle was present; on the other no such structure could be made out. The uveal pigment on the back of the iris ended in a double fold, and there were abnormal adhesions passing between the ligamentum pectinatum and the root of the iris, and remnants of the pupillary membrane were present. There was, besides other opacities in the lens, one at its anterior pole raised above the surface, and evidently due to subcapsular proliferation of the lining epithelium. He thought the arrest

Anterior half of right eye of Case 1. The cornea and sclera have been peeled off, exposing a narrow rim of iris, some tags of pupillary membrane, and an anterior polar opacity of lens. ( $\times 2\frac{1}{2}$ .)

of development of the iris, as well as the other changes found in this eye, could be explained by the theory put forward by Manz, which attributed them to abnormal adhesion or late separation of the lens and cornea, and which mechanically prevented the growth inwards of the iris. He pointed out that there was quite sufficient iris in this case to block the whole of the posterior surface of the ligamentum pectinatum should it have become pushed forwards, and that it was therefore quite possible for eyes in which no iris can be seen to become glaucomatous. In the second case the filtration area in the region of the coloboma of the iris was found more than half closed by a small process with a double layer of pigment on its posterior surface, in which the ciliary body terminated. The ciliary processes opposite the cleft in the lens were directed backwards. This he thought due to the absence of any forward traction by the fibres of the suspensory ligament, which were probably wanting in that position. In the third case there had been a wound of the cornea, through which the whole of the iris and a great portion of the lens had escaped eight and a half months before excision. The eye became glaucomatous, and the nerve was deeply cupped. There was a broad adhesion of the lens capsule to the corneal cicatrix. The advanced position it had thus taken up had drawn forward the ciliary processes, so that the most anterior of them were in contact with the cornea and blocked the filtration area.

Mr. HARTBRIDGE read notes upon a case of Double Neuroretinitis after Influenza. The patient, a girl aged sixteen, suffered from a severe attack of influenza in May, 1891, and a less severe attack in June, 1892. The second illness was soon followed by gradual and progressive failure of vision. The vision is now  $\frac{1}{8}$  in each eye, with correction of some astigmatism. The patient has suffered during the past six weeks from constant headache on the right side. The optic discs are white, blurred and rather swollen; arteries slightly diminished in size, veins slightly tortuous, white lines along some of the large vessels; numerous bright scattered patches in the macular region; no hæmorrhages. There has been no evidence of renal disease; the patient is anæmic, but well nourished.—Mr. CROSS mentioned two cases in young women in whom sight failed a few months after an attack of influenza and whose fundi exhibited changes almost identical with those in the case exhibited. He also alluded to three other cases in which optic atrophy followed close upon an attack of influenza.—Mr. TWEEDY, who had seen one of the cases of atrophy spoken of by Mr. Cross, was of opinion that it was a consequence of influenza. He thought that neuritis after influenza was by no means uncommon and sometimes there was strabismus.—Mr. JULER remarked on the close similarity of the case with one under his own care. He thought, if anything, the

ocular appearances suggested renal rather than intra-cranial disease.—Dr. JAMES TAYLOR said that the appearances in the fundus closely resembled those he had met with in cases of cerebellar tumour. As the case had not been observed in the acute stage, he thought the inference inconclusive.

Mr. WORK DODD presented some observations on the sight of fifty individuals who had made no complaint concerning their eyes.

## DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, OCT. 21ST.

Dr. J. WOODMAN, F.R.C.S., President, in the chair.

Dr. WOODMAN, on taking the chair at this the opening meeting of the fourth session of the Society, congratulated the large number of members present on the very satisfactory position the Society had now taken in the regard of medical men in Exeter and in the county. Dr. Davy then introduced a discussion on Typhoid Fever, and illustrated his remarks by giving details of interesting cases that had come under his notice in private and hospital practice. An interesting discussion followed the reading of his paper.

Mr. H. ANDREW (house surgeon to the Exeter Hospital), then showed two patients with Locomotor Ataxy and who were suffering from Charcot's joint disease (knee). One patient was under Dr. Davy's care and the other under Dr. Blomfield's care, and both cases had been treated with silicate of potash splints with decided benefit. Excellent photographs, taken by Mr. G. Stewart Abram, M.B., were shown and admirably illustrated the particular displacements in both cases.

The annual dinner of the medical men of Exeter and the neighbourhood was held at the New London Hotel, Exeter, the same evening, Mr. Lewis Mackenzie, F.R.C.S., of Tiverton, in the chair.

## TORQUAY MEDICAL SOCIETY.

A MEETING was held at the Torbay Hospital on Oct. 12th, Mr. Karkeek, the President, in the chair.

The PRESIDENT gave an address on Recent Experiences in Sanitary Matters, in which he showed the advantages of early notification and isolation of infectious diseases and the terrible risk daily run by urban communities who obtain their milk supplies from rural districts where no practical control is exercised over such diseases. He cited an instance where great mischief was caused in a town by milk so supplied being polluted with typhoid germs.

Mr. G. YOUNG EALES (hon. sec.) read notes of a case of Ptialism of Neurotic Origin associated with Bilateral Deafness and Dyspepsia. The patient, a man aged sixty-six, a labourer by occupation, had suffered as long as he can remember from deafness and dyspepsia. Four years ago dyspeptic symptoms became aggravated and increased in severity up to June, 1890, when salivation ensued. At first salivary secretion was viscid and variable in quantity; since March, 1891, more profuse and watery, principally from parotid glands, of faint alkaline reaction and sp. gr. 1005. Amount of saliva expectorated averages a pint and a half to two pints and a quarter in the twenty-four hours, and the patient's nights are constantly disturbed by saliva finding its way into the larynx and causing a choking sensation. No obvious cause for deafness; family history unimportant. Has not had syphilis or usual infantile disorders as far as he knows. Has lost flesh considerably since onset of salivation. Appetite voracious; no thirst; bowels sluggish; urine shows constant sp. gr. of 1025 and diminished in volume; no albuminuria; no anæmia; no obvious organic disease. Opium and belladonna preparations, strychnine, galvanism and hyoseyamus afford no relief. Local application also failed. Tannic acid as a gargle checked secretion somewhat for a few days only.

KING'S COLLEGE, LONDON.—The following entrance scholarships have been awarded:—Warnford Scholarships of £75 to E. C. Plummer and C. E. Fenn, and of £50 to J. C. Briscoe; Sambrooke Exhibitions of £60 and £40 to R. P. Williams and P. C. Colls; Clothworkers' Science Exhibitions of £60 and £40 to T. A. Watson and R. E. Shawcross; Rabbeth Scholarship of £20 to P. C. Colls.

## Reviews and Notices of Books.

*Die Syphilis und die venerischen Krankheiten. Ein kurzgefasstes Lehrbuch zum Gebrauche für Studierende und praktische Aerzte.* Von Dr. ERNEST FINGER, Docent an der Universität in Wien. Mit 5 lithogr. Tafeln. Dritte wesentlich vermehrte und verbesserte Auflage. Leipzig und Wien: Franz Deuticke. 1892. [*Syphilis and Venereal Diseases: a Concise Textbook for Students and Practitioners of Medicine.* By ERNEST FINGER, M.D., Docent in the University of Vienna.]

DR. FINGER endeavours to place before his readers in this, the third edition, the pathology of syphilis viewed from the modern bacteriological standpoint. In this he certainly has succeeded, while at the same time he testifies to the gaps in our knowledge of the syphilis microbe. He states at length Lustgarten's method for the demonstration of the bacillus in the tissues as well as in the secretions, and also Doutrelepont's; inoculation and cultivation experiments are still wanting. Dr. Finger does not allow his facts to be warped by theories; he draws attention to the latter on the nature of the syphilis virus only in order to impress the former. The result is a thoroughly reliable treatise and one that can be recommended. The author terms his work "concise" (*kurzgefasst*); as a matter of fact it is most fully worked out under the various headings and sets forth the most recent researches in syphilis and venereal disease. He successively treats of syphilis (acquired and inherited), soft chancre, gonorrhoea, and, lastly, of venereal affections, which sometimes occur singly and sometimes complicate the three leading venereal disorders. Symptomatology, diagnosis, prognosis and treatment are fully considered; the sections devoted to treatment deserve commendation, and the various methods of drug administration are set forth with terseness. The author gives his reasons for preferring one method to the others, but avoids being dogmatic on the subject. The opening paragraphs are devoted to a sketch of the history of syphilis, without, however, adding to our knowledge in this respect. Dr. Finger is a staunch "dualist"; he bases his position on personal observation and supports it by trenchant criticism of the opposite view. The classical division of syphilis into three stages is followed. The first stage is made to include the multiple glandular affections and terminates only with the appearance of the eruption. The polymorphic character of the eruption and its bearing on prognosis are prominently set forth. The prognosis in secondary syphilis as regards the appearance of tertiary symptoms is more favourable in the moist form of the eruption than in the scaly and dry forms, and as the former are more frequently met with in women, tertiary symptoms are less often seen in them.

Dr. Finger does not admit the infectiousness of tertiary syphilis. He regards this stage as a specific cachexia produced by syphilis toxine, and, the severer the symptoms of secondary syphilis are, the earlier, speaking generally, does tertiary syphilis make its appearance. In fact, in severe cases (*ues maligna*) the cachexia is concomitant with secondary syphilis and then tertiary sores are infective, but only by reason of the activity of the syphilis virus of the second stage. Further, if tertiary syphilis were a manifestation of active syphilis, reinfection, which is known to occur during the tertiary stage, would, he thinks, be inexplicable. Dr. Finger lays great stress upon the care which should be bestowed upon the teeth and gums during the administration of mercury, and gives several useful formulæ. He regards inunction as the most, and administration by the mouth as the least, favourable method of placing the patient under the influence of mercury. Under tertiary syphilis are described the various gummatous affections that are met with in the different organs and structures—including

the nervous system—of the body. Dr. Dimmer contributes a section on Syphilitic Affections of the Eye and its Adnexa. In the section of Inherited Syphilis the various points concerning infection on the part of mother and child are well discussed. Dr. Finger considers treatment should be continued at least for two years uninterruptedly, and then at intervals during the third year as long as no evidence of relapse is present. He regards the various sulphur baths as most beneficial in the tertiary stage or at the end of an energetic course of mercurial inunction. Marriage should not be permitted till three years after infection, and then only provided no symptoms had occurred during the third year. Even then a course of mercury might be with advantage prescribed, followed by the administration of potassium iodide. Tonic treatment is also insisted upon, and the formulæ of Zittmann's decoctions (strong and weak) are given *in extenso*. Dr. Finger denies that there is a specific virus producing the soft chancre. He regards it as the product of suppuration—i.e., of pus cocci—and states that the pus of acne, scabies and impetigo may produce soft sores in healthy subjects. He mentions Cooper, Bumstead and Taylor as having demonstrated these points some years ago. He alludes to Ducrey's bacillus, and draws attention to the want of proof of its relation to *ulcus molle*.

Dr. Finger fully admits the etiological relationship of Neisser's gonococci to gonorrhoea. He gives easy methods for recognising their presence in suspicious discharges. The complications of gonorrhoea are fully treated, and Dr. Dimmer describes the blennorrhœic affections of the eye. Under the division, "Venereal Affections occurring singly or complicating the three chief Venereal Disorders," Dr. Finger describes balanitis, vulvitis, venereal warts, phimosis, paraphimosis, lymphangitis and adenitis.

In conclusion, we may remark that the subject matter is clearly and concisely stated. The author's style is lucid, in marked contrast to many German medical works. English readers whose acquaintance with German may not be very extensive will have no great difficulty in arriving at the writer's conclusions. The type is clear, and a comprehensive index adds to the value of the work. The five coloured plates are good specimens of German work, and represent various lesions of syphilis, soft chancre, incipient stricture, gonococci and syphilis bacilli.

*Inoculation a Preventive of Swine Plague.* By F. S. BILLINGS, M.D.

SINCE M. Pasteur introduced protective inoculation for anthrax by means of specially prepared virus or "vaccine," as he unfortunately named it, efforts have been made to protect the porcine species in a similar manner from the intensely infectious and extremely destructive disease generally designated swine plague and swine fever. On the Continent much attention has been given to the subject, and, according to report, a large measure of success has attended the inoculation of cultivated virus into herds of pigs exposed to infection. In the United States of America, where the scourge rages almost continually and causes startling havoc, protective inoculation has likewise been tried on a somewhat extensive scale, and, according to one account, which has been disputed, with beneficial results. For some time the discussion arising from this difference in conclusions has been carried on in a somewhat acrimonious spirit, and the book just issued by Dr. Billings is the culmination of the dispute. In it, while adducing evidence to show that his mode of inoculation of pigs to preserve them from the malady has been on the whole satisfactory, he is unsparing in his denunciation of the administration of the United States Agricultural Department, which he stigmatises as a public scandal. He is particularly severe on the secretary

of that department, who seems to have been the chief offender. The language employed by Dr. Billings is very vigorous, much of it is what has been of late euphemistically termed "Saxon," but which gentlemen and men of science might easily dispense with in favour of milder and equally effective terms. More harm than benefit results from such hard-worded altercations, and it is matter for regret that Dr. Billings, who has done some really good work as director of the Patho-biological Laboratory of the State University of Nebraska, should have committed himself to the publication of a book that reveals a very unpleasant state of affairs. It is to be hoped that his system of inoculation will be submitted to a fair and impartial examination and the evidence he gives thoroughly tested, so that the truth may be arrived at. Unfortunately, the wide prevalence of this plague of swine in some of the States affords ample opportunity to realise this desire, and we are certain that if the public interests are kept in view by both sides we shall hear no more of the public scandal. It might be remarked that as the disease is so common in this country, and inflicts so much damage on the pig industry, inoculation should be tried here. At present nothing is done, the control of the epizootic disease being left to the local authorities, who may do little or nothing in checking it just as the spirit moves them.

*A Manual of Veterinary Physiology.* By Veterinary-Captain F. SMITH, M.R.C.V.S. London: Baillière, Tindall and Cox. 1892.

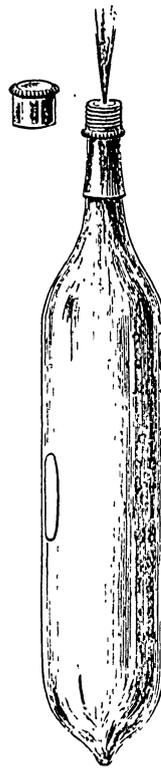

A HANDY book on physiology for the special use of veterinary students was much needed, and the one now prepared by Veterinary-Captain Smith, who is well known from his "Manual of Veterinary Hygiene" and other contributions to veterinary literature, as well as from his prominent position of professor at the Aldershot Veterinary School. The work will commend itself to those for whom it was written by its conciseness and the able manner in which the important facts relating to the physiology of some of the principal domestic animals are dealt with and arranged. For this reason it will probably supplant to some extent Meade Smith's "Physiology of the Domestic Animals," which treats the subject in greater detail. Mr. Smith appears to have availed himself of the assistance of many of the best authorities, English and foreign, and so has made the manual more complete and reliable as a work of reference, while many of his own observations are original and interesting. The chapter on Digestion is very instructive to horse owners, as is also that on the Locomotor Apparatus. In reading the chapter on the Physiology of the Horse's Foot—a most wonderful and highly important organ to study—it is stated that a horse's sole carries but little of its weight, only the margin, which is immediately in contact with the wall, assisting. "When we remember that the sole is concave it will be clear that it has some other function than that of weight-bearing to perform—its function is to protect the sensitive sole and pedal bone." We should imagine that the entire sole was designed to support weight, and that its being concave was rather an argument in favour of its utility in this respect. The strongest bridges are those which are concave underneath, and the author must have overlooked the fact that the human foot has a concave sole, and yet it has no analogous structures like those of the horse's foot to protect. No doubt one of the uses of the horny sole is to shield the sensitive parts resting on it, but it must also support a good share of the weight, like the sole of many other species of animals.

There are many curious and suggestive remarks to be found interspersed throughout the 400 pages of which the work is composed, and that at the termination of the last chapter is one of them. Speaking of the causes of death the result of disease, it is mentioned that, no matter what the cause may

be, horses seldom die quietly; "by far the majority of them leave this world in powerful convulsions, fighting or struggling to the last, lying on their side and galloping themselves to death. Rarely, indeed, does one witness a quiet death in horses, and the subject presents a problem for solution by the physiologist. Shortly after death rigor mortis appears, and within an hour or two tympanites of the abdomen is apparent, reaching such a degree in a few hours that post-mortem rupture of the diaphragm is exceedingly common. The explanation of this disturbance is the enormous amount of gas generated by vegetable food."

## New Inventions.

### ADMINISTRATION OF CHLORIDE OF ETHYL.

A USEFUL and ingenious instrument for the administration of chloride of ethyl as a local anæsthetic has been devised by Dr. Bengué of Paris. Hitherto this anæsthetic has been supplied for this purpose in small glass capsules, which required to be broken before the fluid could be applied to the skin. This, however, is overcome by placing it in a stoppered bulb. Having unscrewed the stopper the warmth of the hand will send out the spray. If applied at a distance of a quarter of an inch for thirty or sixty seconds to a spot, the skin first becomes pink coloured, then red, and finally white, when local anæsthesia is complete. The anæsthesia will last for more than two minutes. As a means of applying an ethereal spray to the spine in chorea, or for the relief of certain neuralgias, the advantages of this apparatus are very obvious. It is cheap, convenient, economical and handy. For the minor operations which present themselves in dentistry and in minor surgical operations, such as the incision of abscess, carbuncle, evacuation of subcutaneous tumours, removal of foreign bodies and the like, the use of the spray will be found to be exceedingly effective. The sole agency for the United Kingdom has been secured by Mr. B. Kühn, Eastcheap, London, from whom the bulbs charged with ethyl chloride and ready for use may be obtained.

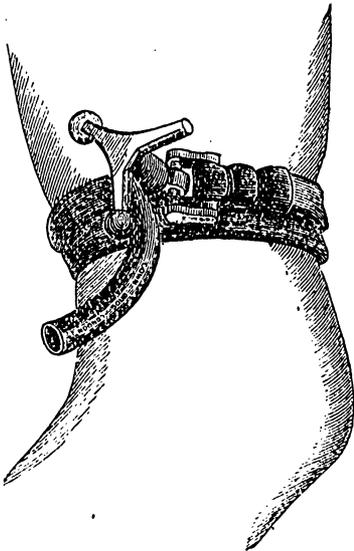

### IMPROVED TRUSS FOR HERNIA.

MESSRS. SALT AND SONS of Corporation-street, Birmingham, have submitted to us an improved hernia truss of their construction with patent celluloid pad. The object of this invention is to impart an increased elasticity to the surface of the pad or cushion, to lighten it, and to provide by the use of suitable material a truss presenting a perfectly smooth surface, and capable of being easily cleansed. To effect this pads are constructed entirely of celluloid, a material which when rolled in thin sheets becomes elastic. These pads are made hollow, the back of the pad being thickened to give the necessary rigidity, for attachment to the spring, the front or convex portion which comes in contact with the body being of the material sufficiently attenuated to present a highly elastic surface. The celluloid used is polished and semi-transparent, and the spring is covered with a sheath of the same substance, which being sealed at each end effectually protects it against the action of the perspiration, presenting also a perfectly smooth surface to the body, and thus entirely

doing away with the ordinary leather cover, which may become a receptacle for dirt and infection. The entire surface of the appliance is of celluloid, and it can therefore be washed daily. Owing to the hollowness of the pad, and the thinness of the coating of the spring, the truss is extremely light, and especially is the surface presented by the pad to the hernial ring smooth, elastic and comfortable. Peculiar attention has also been paid to the shape of both pad and spring, and the instrument appears to be calculated to adapt itself to the body and fulfil its purpose.

#### SAMWAYS' TOURNIQUET CLIPS.

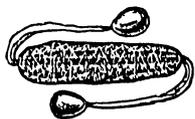

THE tourniquet forms a very important part of the armamentarium of the surgeon and any improvements which tend to render its application at once simple and efficacious are to be commended. The tourniquet before us, patented by Messrs. Down Brothers, certainly comes within that category. The band is of strong rubber and by a simple arrangement can

be fixed at any point without twisting. The clip by which fixation is effected is of two patterns—the anchor pattern and the grapnel. Whichever may be used equal security against slipping can be secured. Its simplicity and the ease with which it can be applied to and removed from the limb will render it acceptable to most surgeons.

#### FAVETS' LOOFAH FLESH RUBBERS.

WE illustrate below what will prove to many a useful adjuvant to the morning douche—"the Loofah Flesh Rubber." It has for its object stimulation of the cutaneous circulation, slowness of which in those of feeble hearts subtracts so largely from the utility of the daily bath, and manifests itself by coldness of the hands and feet and a general feeling of chilliness. By the use of these patent flesh rubbers these unpleasantnesses may be avoided. While it is a valuable aid in the bath it may be used for dry friction. The rubbers are supplied in various forms to suit different skins.

They may be had plain with tape throughout double and handles, or with towellings and fancy attachments at both ends, and they may be half covered or entirely with towelling, which can be removed if desired. They will be found useful for stimulating the circulation in the lower extremities. They may be obtained from the patentee and manufacturer J. Favet, Seething-lane London

### THE TREATMENT OF MYXEDEMA.

To the Editors of THE LANCET.

SIRS,—That considerable interest is taken in the method of treatment of myxœdema which I have found so beneficial in a case under my care at the Royal Free Hospital, as noted in THE LANCET of Oct. 15th, is shown by the large amount of correspondence I have since had on the subject. Among other questions I have been asked whether the thyroids were given raw or cooked, how they were prepared, how procured, from what animal they were obtained. The glands I have used were from the sheep, but I do not think it matters whether sheep's, pig's, or bullock's thyroid is used, except that the latter is larger than is required for the purpose. I found both the hospital butcher and my own butcher were quite ignorant as to where or what the thyroid gland was. They knew the thymus by the name of the throatbread, and sent that at first. The simplest plan to get the thyroid was to have the larynx and trachea with the muscles sent entire soon after the animal was killed. As the part is of no value to the butcher, he should be able to supply it for quite a small sum. The thyroid gland can easily be separated from the other parts. In the sheep the lobes are rather smaller than in man and the isthmus is rudimentary. The lobes can be easily distinguished from the muscle by their oval shape and darker colour, although this varies in different cases. I have throughout given the glands raw, except at the very outset, when they were cooked by mistake. I cannot say whether they would have any effect if given thoroughly cooked. That could only be found out by experiment; but I can see no objection to very slightly cooking them—for instance, by frying. It is highly probable that thorough cooking would entirely destroy their effect. The mode of preparation in my case has been simply to mince the gland finely and give it either plain or with a little brandy. The addition of the latter was found to make it more acceptable to my patient, and also diminished the tendency to nausea which she experienced when she knew she was having something raw. Currant jelly might make it more palatable. As mentioned, I gave my patient two whole thyroids (four lobes) every day at first, but found this was too much, as the pulse rate after a time was much increased. I do not think it will be necessary to give the patient more than one thyroid every other day.

Some may prefer to employ a home-made extract of the gland, which may be prepared by mincing up the thyroid, placing it in a mortar with a little crystallised sugar and glycerine, rubbing it up with a pestle, then adding a little water and, after allowing it to stand an hour or two, filtering through muslin or calico. It is, of course, possible that a stable thyroid extract may be obtained which will in practice be found more convenient than the process I adopted. The important point is to have shown that the thyroid gland contains something which, given by the mouth, has as distinctly curative an effect as hypodermic injections of thyroid juice.

In regard to my patient I may add she has now left the hospital, but attends there twice a week to have a thyroid gland. She looks and feels very well. One of my colleagues who was lately taken to see her without being told what the case was actually did not recognise it as a case of myxœdema. She has lost two stone in weight, having previously scaled over eleven stone. One of the most curious effects is the growth of hair on the crown of the head, where only a couple of months ago she was bald. The hair is growing so thickly that at present the scalp somewhat resembles a doormat. Her hands, which completely desquamated, are quite normal in appearance. Her face exhibits no sign of its former alteration. Her spirits are good and she is quite lively in her movements. I am glad to know that the treatment is being adopted in a considerable number of cases, not only of myxœdema, but in sporadic cretinism, and I look forward with confidence to its effects in uncomplicated cases. I may be allowed to point out that many cases of myxœdema are complicated by the coexistence of other diseases, and that in these only partial benefit can possibly result.

I am, Sirs, yours truly,

HECTOR W. G. MACKENZIE, M.D., F.R.C.P.

Oct. 22nd, 1892.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 29, 1892.

IN the history of medicine, full as it is of vague fancies and erroneous assumptions, there is one period which stands as the inauguration of a new epoch, which marks indeed the birth of ideas that have never ceased to influence our conceptions of animal function and its derangements. The lessons taught by the life of HARVEY and his work, which are annually commemorated in the College of which he was the greatest son, have seldom been more amply and fittingly brought home to us than they were by the orator of this year in his highly finished and discriminating address. In Dr. BRIDGES, as a representative of that branch of medicine which in the present day is recognised as an essential department of the State, and for which there is a future of almost unlimited expansion, the Royal College of Physicians of London found an orator who seems to have grasped clearly the conditions under which HARVEY laboured and the far-reaching efforts which have flowed from his memorable discovery of the circulation. As Dr. DICKINSON last year pointed out, and as was equally dwelt on by Dr. BRIDGES, the age in which HARVEY flourished was one of exceptional fertility in men of genius; but one of the most striking incidents in the career of the first of physiologists was the fact that he must have come under the influence of GALILEO, who was attracting students from all quarters to his classes at Padua when HARVEY went there to study. Dr. BRIDGES thinks, and with reason, that the doctrines of GALILEO, embodying the principles of physical science and forming the basis of the modern doctrine of the conservation of energy, cannot but have impressed the young English student, and may possibly have materially assisted him in his subsequent study of the forces at work within the living body. Whilst GALILEO, then, was breaking down the old dogmas and revealing the truths of mechanical science, it was reserved for HARVEY to dispel at one word the fantastic ignorance that prevailed concerning the primary facts of biological science. The fact that SERVETUS and COLOMBO on the one hand, and CESALPINO on the other, came so near doing what HARVEY did and yet remained so far away from the real explanation of the function of the heart and bloodvessels makes manifest the strength of the hold which preconceived ideas had upon them; whilst it also serves to show how great must have been the scientific spirit which could break away from those dominating influences and arrive at a first and bold generalisation after patient and diligent observation and experiment. HARVEY realised that the heart was a muscular organ and that the blood moved through the body "in a circle," because the facts which he saw were perceived through no hazy medium or authoritative dogma, but with the clear vision of an unprejudiced observer. To us, in these days, there must often come the occasion—not indeed fraught with such momentous issues, but like in essence—when the

principle underlying all HARVEY'S work must find its application. For it is the root-principle of all scientific work which can only be rendered of service when combined with an absolute freedom from bias on the part of the observer. Well and truly may Dr. BRIDGES say that scientific medicine dates from HARVEY.

In reflecting on the effects which this discovery had upon medical thought and practice Dr. BRIDGES dwelt upon the fact that it introduced vital functions within the sphere of law, and that it was adopted by DESCARTES as a main support of his mechanical philosophy of vital action—a doctrine which failed because of its narrowness. Still, as was pointed out, the immediate effect of HARVEY'S work did not result in any striking progress, because no attention had then been paid to the chemistry of the body, partly owing to its being lost sight of in too great concentration of thought upon vital "mechanics." When, however, chemistry was re-born in the eighteenth century, which also saw the rise of physiology (i.e., biology), then indeed was the full value and meaning of the circulation of the blood properly appreciated. We may smile now at the various "schools" (which were so happily sketched by Dr. BRIDGES) of opposing theories of the functions of the body and their application to its diseases, but we must not forget that they were each of them the expression of ideas arising out of the introduction into the study of vital actions of many new and true facts; and in the light of its past history it would be vain indeed to think that medicine will not traverse many another period of crude notions and partial theories before it can attain a sure position among the sciences. There are scope and range enough for many a discovery which may throw quite a new light upon certain phases of animal life and function, which may create a revolution in ideas similar in kind if not so vast in extent as the change instituted by HARVEY. Of one thing at least we may be sure, and that is that the principles which he laid down in all his research will, if adhered to with similar fidelity and single-mindedness, lead us nearer to that goal which ever seems to recede the wider knowledge grows—that, namely, which is the aim of all the sciences, the revelation of the Truth that lies hidden in the heart of Nature.

UNLESS legal redress is to be sought by those who think themselves aggrieved in the controversy which has arisen out of the recent meeting of the Church Congress, no harm would accrue to science or to morals by letting it drop for the present. No good comes of polemics conducted at such high temperatures; and the pyrexia of controversy is very like that of certain forms of continued fever—it requires time for abatement. Defervescence takes place only gradually and after the lapse of weeks; indeed, we doubt whether the discussions and processes of a law court—though doubtless acceptable to lawyers and interesting to the public—with all the leading *savants* and ecclesiastics as witnesses, would much further the progress of truth and justice in this matter; they would rather, on the contrary, tend to obscure the clear appreciation of the questions at issue. The wordy strife which has been going on in and since the Church Congress has been rough, but it has not been without its effect on all sensible and moderate people, and, after all, they are the people in this country who

decide controversy and generally decide it with a fair recognition of the merits of both sides. Undoubtedly rough things have been said and forcible language has been employed. Mr. VICTOR HORSLEY has used against a lady the little word of three letters which jars on polite ears. He would have done better to have avoided it ("Gentle words are always gain"). There are synonyms which would have served; and his case is so overpoweringly good and strong that it does not need to be bolstered up with disfiguring nouns and adjectives. We are quite alive to the provocation he received. The public does not know half the hysterical abuse that has been heaped on scientific men in England—and even on their wives—who defend or use experiment on animals under a complete conviction of its uses. But, even so, they must not lose self-control. They may decline controversy with such unfair or unworthy opponents and explain their ample reasons for doing so, but they should rely solely and confidently on their own character and work and not on the strength of unparliamentary monosyllables. With this qualification the case for humane experiments on lower animals with a view to elucidate the nature of disease or the action of remedies has been completely established by the recent discussions. Sensible men—and women too—begin to see that there are deep reasons for such experiments in the solidarity of the animal creation, in a great community of interests between man and his lower fellow creatures, and in the obvious right of man—more than a mere right founded on might—to use the lower creatures for medical purposes. Such people begin to see that a great and beneficent profession, whose nature and function it is to *heal*, does not inflict suffering wantonly, and that it has incalculably good results to show for the slight pain that it does inflict. The poor appearance in argument of leading divines as compared with that of leaders of the profession has not increased respect for them as guides in moral questions. The exposure of the fact that when extreme opponents of experimentation on animals are bitten by suspected dogs they repair to Mr. VICTOR HORSLEY for guidance, sanctioning him even to sacrifice two rabbits to relieve their fears, shows that they are either very selfish or very superficial in their views, or that they conceive of themselves as having a strange authority to grant medical men such indulgences. The ordinary fair-minded man has had brought home to him with great force that, whereas bishops and clergymen have rarely a word to say against forms of sport which must necessarily cause pain to animals, they empty all their vials of wrath on those who can be shown to inflict the minimum of pain on animals, and this only for the most benevolent of purposes, and in the carrying out of experiments which have given precision to physiological knowledge, and have suggested operations which have saved many human lives and give promise to save life on an enormous scale, and to strengthen the whole foundations of medical science. Bishop BARRY, in *The Times* of Monday, is candid enough to say that he "questions the moral right" to perform such experiments on animals even in hope of the advancement of knowledge and physical benefit to mankind. Bishop BARRY was Principal of King's College for fifteen years, and during that period had as colleagues Professors RUTHERFORD, GERALD YEO, Sir JOSEPH LISTER, FERRIER and WATSON CHRYNE, all of whom were well known as having

made experiments on living animals. Bishop BARRY must have forgotten that such experiments had been made at King's College or he could not now have stigmatised his colleagues as having been demoralised and cruel in the making of these. Did he ever ask them as to the details of their experiments or object to their laboratories being used for this purpose? It must be pointedly brought home to him that he was constantly meeting these colleagues and at that time made no complaint as to their investigations, and he cannot escape from the dilemma that he either was unaware of the work then done at King's College or that he did not oppose these methods for the advancement of medical science as cruel, demoralising and unnecessary. He was in daily communication with those who were well known to everybody as experimenters, and whose researches were duly made public. These members of our profession, then, colleagues of Bishop BARRY, must be included among those against whom he has formulated his unkind accusations. At the present time Bishop BARRY is a Life Governor and Member of the Council of King's College, and we are told that among the most recent developments of the College laboratories for bacteriology, surgical pathology and neuro-pathology have been established. Experiments on living animals, if these laboratories are to be of any value, must be and are carried on. We only notice this as another instance of the inconsistencies into which members of the Anti-vivisection Society, who do not take regard of all the bearings of the question, are apt to fall. Bishop BARRY could have known all about vivisection at first hand from his colleagues, and is little to be pitied when he finds himself in an inexplicable position owing to his having trusted in the incorrect narratives circulated by the officials of the Society. Another prelate once said that if an experiment on the life of a rabbit would save a human being he could not approve it. Fortunately one bishop has told us that for the preservation of his voice he does see his way clear to give orders to his butcher which involve the killing of animals much larger than rabbits.

It is with no insincerity that we express our regret at seeing religious leaders so weak and unpractical in a practical and earnest age. Two things strike us in these bold opponents of science in its most urgent and benevolent form—for is not medical science urgent and benevolent above all others? They are characterised by two great mental defects which make us almost hopeless of their conversion. One is their want of *faith*. The scepticism of these men is amazing. They have absolutely no faith in the very cream of the medical profession. The testimony of men like Sir ANDREW CLARK, Sir JAMES PAGET and other leaders, to say nothing of the rank and file of the profession that is face to face with sickness and death by night and day, has no effect on men like Bishop BARRY. We are not going to use strong language about men whose profession is that of faith, but who are deplorably sceptical of a whole class of the truest witnesses, of men who see deeper into life and morals than many clergymen do. How men who believe so much can be so sceptical puzzles us. We cannot understand men who believe in GOD having no faith in their own fellow creatures. The other great defect in "anti-vivisectionists" is the entire *want of the sense of proportion* which they display. They allow that men may kill an animal to afford them pleasure at the dinner table or on the *ors*, as does a butcher or a sportsman, but deny

that a physician may perform an experiment on the same animal, on a rat or a rabbit, to save life. The want of the sense of proportion here is quite ludicrous. There is a certain difference, despite these theologians, between the value of a sheep and that of a man. This point of proportion is much insisted on in a certain book whose authority the clergy all recognise. The book declares that a man is of "more value than many sparrows," and that he is "*much better* than a sheep." But our clerical friends have no sense of proportion and cannot see that the infliction of pain on an animal is justified if necessary to save the pain of all other animals and of man, who is "better" far than them all. These defects in common men would be of less consequence; but in men who profess to be moral guides they are almost as grave as a want of charity. To think that these defects should be exhibited in clergymen—in men who pose as the moral teachers of mankind—is serious matter for reflection for all who wish well to the cause of morals and religion. If such defects are not remedied it is not the medical profession that will suffer, as it will certainly not be diverted from its own methods in the unravelling of the mysterious processes of disease.

AFTER a trial lasting five days THOMAS NEILL—or more correctly THOMAS NEILL CREAM—was convicted at the Old Bailey on Friday, Oct. 21st, of the wilful murder of MATILDA CLOVER. There were seven counts in the indictment—four charging him with having killed severally ELLEN DONWORTH on Oct. 13th, 1891; MATILDA CLOVER on Oct. 20th, 1891; and ALICE MARSH and EMMA SHRIVELL on April 12th of the present year; two with having sent threatening letters to Dr. BROADBENT and Mr. JOSEPH HARPER demanding money with threats; and lastly, one of having feloniously attempted to administer to LOUISA HARVEY a large quantity of strychnine with intent to murder her.

The prosecution elected to proceed first with the case of MATILDA CLOVER, inasmuch as the evidence was more varied and complete than in those of the others. It was urged by counsel for the defence that each case should be taken on its own merits, and that the facts as regards the alleged murder of DONWORTH, MARSH and SHRIVELL were inadmissible as evidence against the prisoner in the case of CLOVER. Mr. Justice HAWKINS, with sound common sense—and, as it seems to us, sound common law—ruled that if the evidence was corroborative it ought to be received. In each instance the victim belonged to the class of "unfortunates," and in each strychnia was the means by which death was brought about.

The convict was born at Glasgow in 1850. When two years of age he was taken to Canada. He received a medical education at McGill College, Montreal. He remained abroad until October, 1891, when he arrived in England. His career in America and Canada seems to have been a catalogue of crime. A self-professed abortionist, he was found guilty of murder in the "second degree," having killed a man by administering strychnine. For this he was sentenced to penal servitude for life, which was afterwards commuted to seventeen years. He remained in prison from 1881 to 1891, when on his release he came to this country and resided at Lambeth Palace-road. On Oct. 9th, 1891, he was seen by two wit-

nesses to accompany CLOVER to her lodgings. On Oct. 20th a man answering to the description of NEILL, although his identity on this occasion could not be sworn to, went to the house with her and remained for some time. After his departure CLOVER went out again and returned between 1 and 2 A.M. At 3 A.M. the servant heard her shrieking and called the landlady. Up to the time of her death, a period of five hours and three-quarters, she remained in a state of agony, suffering from spasms or "convulsions." Her consciousness remained, for she expressed the belief that she had been poisoned, that she would die, and asked to see her child. In the absence of Mr. GRAHAM, who was sent for, Mr. COPPIN, Mr. M'CARNEY'S assistant, visited her. Mr. GRAHAM had attended her for nine days before her death for alcoholism, and, from his knowledge of her ailments and from the facts communicated by the landlady and Mr. COPPIN, he came to the conclusion that she had died from "delirium tremens and syncope." The death was registered and the body interred. Shortly after this episode NEILL asked Miss SLEAPER, the daughter of his landlady, to make inquiries at CLOVER'S residence if the latter was dead, and told her that she (CLOVER) had a child living with her. Upon Miss SLEAPER demurring, NEILL said he would take the letter himself. The next link in the chain of evidence was also forged by the criminal himself; for on Nov. 28th, a month after CLOVER'S death, he sent, in a false name, a letter to Dr. BROADBENT charging him with having murdered her by *strychnine* and demanding money. This letter was sent to Scotland Yard. Now up to this time it was not even suspected that CLOVER had died a violent death, much less that poisoning by strychnine was the form it assumed. About Easter, 1892, NEILL made inquiries of Miss SLEAPER concerning the position of Mr. HARPER, son of Mr. HARPER of Barnstaple, who resided in the same house. Soon after he sent a letter—again under an assumed name—to Mr. HARPER, saying that he had evidence that his son had poisoned MARSH and SHRIVELL (who died April 12th, 1892) and attempting to levy blackmail. On May 4th he told Mr. HAYNES, an acquaintance, that Mr. HARPER had poisoned CLOVER, MARSH and SHRIVELL as well as "LOU" HARVEY. HAYNES communicated with the police, and on June 3rd NEILL was arrested and charged with having demanded money with threats from Mr. HARPER. Then followed the result of Dr. STEVENSON'S analysis of the exhumed remains of MATILDA CLOVER. Strychnine was detected by chemical, physical and physiological tests.

It may be added that in January, 1892, NEILL went to Canada and returned to England on April 9th. A remarkable fact transpired in connexion with the case of HARVEY. NEILL met her by appointment on the Embankment, as it turned out for the alleged purpose of giving her pills to remove some spots from her face. He requested her to take them then and there, but she only feigned to do so. No doubt he believed, as in the other cases, his fell purpose had been effected and that HARVEY had died, for we find him telling HAYNES of her sudden death in the streets. It was only during the hearing at the police-court of the charge against NEILL of having poisoned CLOVER that the woman HARVEY came upon the scene and tendered her evidence. It will be seen that following the deaths of CLOVER, MARSH and SHRIVELL, NEILL falsely accused others of having mur-

dered them, and accompanied his accusations with threats to extort money as the price of secrecy. To add to his villainy he went so far as to induce his *fiancée* to write some of the letters. In no instance, however, does he seem to have intentionally disclosed his identity, or taken further measures to have his demands satisfied. In his possession were found the names and addresses of the girls MARSH and SHRIVELL in MARSH's handwriting. This was written on paper having a foreign watermark similar to that on which he had penned his letter to Mr. HARPUR. He had also shown to HAYNES the same address in a book; but this, as well as a box of capsules, disappeared. There was ample evidence that he had strychnia in his possession, for pills containing this drug were found in his rooms. Moreover, on several occasions he had purchased nux vomica in quantity beyond his individual need. Analyses in the cases of DONWORTH, MARSH and SHRIVELL showed that fatal doses of strychnia had been administered.

Having stated the salient facts proved at the trial, several points of forensic interest may now be considered. In the first place, it is a painful duty to subscribe to the remarks made by the judge and the Attorney-General in regard to the giving of a death certificate by Mr. GRAHAM. No doubt he believed on ample evidence that CLOVER was suffering from alcoholism, but this surely did not warrant him in ascribing the death to "delirium tremens and syncope." A close inquiry into the final sufferings of the deceased should have suggested at least that the symptoms were consistent with a theory other than "death from natural causes"—if alcoholism may be so termed. The girl was about as usual on the night preceding her death. She had shown no signs of delirium. During her agony she was not only sensitive but sensible. Delirium tremens does not usually end fatally within a few hours. Mr. GRAHAM certified, as we gather that he last saw deceased on Oct. 21st; but it was only her dead body that he viewed. The above is a regrettable instance of the shortcomings of the legal requirements as to the certification of death in this country.

Fortunately for the cause of justice strychnia, though a vegetable poison, has great resistance to decomposing forces. MATILDA CLOVER had been buried between six and seven months before the analysis of her remains was conducted, and yet Dr. STEVENSON was able to show the presence of the alkaloid in the various tissues and that, too, in quantity representing the administration of a fatal dose. Mr. GEOFFRIGAN for the defence argued consistently with the *fas* of advocacy when he attempted to discredit Dr. STEVENSON's testimony, but he was strong in a lost cause, for in skilled hands proof of the existence of strychnia is not difficult. His contention that the physiological test with the frog was inapplicable to the question of poisoning in the human being, though ingenious, was certainly at variance with accepted scientific teaching.

MATILDA CLOVER lived longer than do most persons who have taken a lethal dose of strychnia; but then there are no absolute limits within which death must occur. The quantity ejected in the vomit (if any), the presence or absence of food in the stomach, the simultaneous action of antidotal or antagonistic drugs and the power of absorption by the mucous membrane at a given time are important factors in determining the duration of life.

The jury had before them evidence more than enough to substantiate their verdict without being called upon to fix a motive to the crime of which they convicted NEILL. To the psychologist, however, his case is one of absorbing interest. That he willed to do the murderous deed, or, in other words, acted under conscious motive there appears to be no shadow of doubt, leaving aside the absurd legal proof of criminal responsibility—"the knowledge of right and wrong, or of the nature and quality of the act." Nor can we argue in NEILL's favour impulsive homicidal insanity as usually understood. At the same time it is difficult to believe that the convict perpetrated these unutterable crimes with a mind constituted to realise their enormity and with a power of will equal to inhibit their commission. As to what motive may have impelled him to the commission of these singularly cold-blooded murders we are at a loss to conceive. Perhaps after all there is some reason in the lines:—

How oft the sight of means to do ill deeds  
Makes ill deeds done.

## Annotations.

"Ne quid nimis."

### INTERNATIONAL MONUMENT TO SEMMELWEIS.

A MEETING was held in the library of the Royal College of Physicians of London on Monday, under the presidency of Sir Andrew Clark, the object of which was to combine with all admirers of Semmelweis—"the father of antiseptic midwifery"—to raise in his native city of Budapest a monument to this great pioneer of antisepticism. It is nearly fifty years since Semmelweis demonstrated the septicæmic nature of puerperal fever, and for many years his work was appreciated by only a few followers and his name was almost forgotten. We rejoice to think that his professional brethren in Hungary have determined to raise by international subscription a memorial to their distinguished countryman, who, like many a martyr, was not appreciated while he lived. Dr. Routh was the first to bring before the profession in this country the important work of Semmelweis in an article published in the *Transactions of the Royal Medical and Chirurgical Society* for 1849, and his name and work were revived some seven years ago by his countryman, Dr. Duka, now resident in London, and formerly Surgeon-Major in the Bengal Army. In sympathy with this movement we think a few details of the life of him whose work it is intended to commemorate may be of interest at the present time. Ignatius Philippus Semmelweis was born on July 17th, 1818, and at the age of nineteen he entered the University of Vienna and graduated in 1844. About two years afterwards he became temporary assistant professor in the maternity department of the great General Hospital at Vienna under Professor Klein. The records of the puerperal mortality had been at times very alarming, sometimes 16 per cent., or even higher. There were two clinics, one attended by students and the other by midwives, and the average mortality of 9.29 per cent. in the clinic attended by the students, who also attended the dissecting-room, compared with the lower mortality of 3.38 in the midwives' clinic attracted his attention. All kinds of theories were advanced to explain this difference. So bad was it in the clinic of Dr. Klein when Semmelweis became the assistant that "patients, on finding themselves inmates of the dreaded clinic, fell on their knees and with clasped hands begged to be allowed to return to their homes." Semmelweis was of a highly sensitive nature and he most graphically describes

the scenes: "I myself was terror-stricken when I heard the sound of the bells [rung in the wards when the priest was administering the last sacrament to the dying]. A deep sigh rose in my breast for the unfortunate mother, who was the victim to a cause hitherto unknown. This worked on me as a fresh incentive that I should to the best of my ability endeavour to discover the mysterious agent, and a conviction grew day by day that the prevailing fatality in the Clinique No. 1 could in no wise be accounted for by the hitherto adopted etiology of puerperal fevers." The view then taught was that these epidemics were due to "atmospheric, cosmic or telluric influences." He, following the truly scientific method, showed that this theory was unable to explain the facts, for the fatal fever did not exist in other parts of Vienna. Overcrowding was suggested, but the clinique of the midwives contained more patients than the students. Then the theory of fear was advanced as a cause of the unfavourable result. Protracted labour was fatal in all cases in the one clinique, whereas in the other this circumstance had but little effect. The whole story of rejection of theory after theory is a most interesting example of the exercise of that true scientific spirit called by Sir Andrew Clark "the scientific instinct." Semmelweis's friend Professor Kollatschka died of a dissection wound. "Then the revelation came to me," he said: "Kollatschka's fatal symptoms unveiled to my mind an identity with those I had so often noticed on the deathbed of puerperal cases." At last he felt able to explain the etiology and at once enunciated the doctrine of septicæmic poisoning and ordered the use of antiseptics—namely, the washing of the hands with chlorine water or chlorinated lime-water before proceeding to examine patients. The mortality immediately before this was 12·24 per cent., and in the course of six months it fell to 3·04 and afterwards to 1·27 per cent. After careful observation he further discovered that "not particles from dead bodies alone, but any material in a state of decomposition proceeding from a living organism, even air contaminated from such sources, may generate symptoms of puerperal fever." Very soon his term of office expired, and, by a combination of jealous *conferes*, his reappointment was resisted and he had to quit the field of his scientific observations and betake himself to his native city in 1850. He there wrote his great work "Die Ætiologie," in which he also propounded the doctrine of auto-genetic infection. He was appointed professor of midwifery in Budapest. Though he was conscious of having discovered and set forth a great truth, yet his teachings met with considerable opposition, and his sensitive nature gave way. He was removed to an asylum in Vienna in July, 1865, and on Aug. 17th he passed away, the actual cause of death being pyæmia: a strange coincidence that he should die of a disease to the elucidation of which he had devoted the best years of his life. Such is the story of this most remarkable man, and we trust that the profession in this country will join with all admirers of true heroism in establishing this memorial. By the limitation of the maximum subscription to one guinea, suggested by the committee at the meeting on Monday, the rank and file of the profession, who have benefited most of all by Semmelweis's discovery, will, we trust, unite to send a contribution worthy of our country, feeling assured that in assisting in honouring him we are doing honour to our profession.

#### ANNUAL GENERAL MEETING OF FELLOWS AND MEMBERS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Fellows and Members of the College who are interested in the reform movement are reminded that the annual general meeting of Fellows and Members of the College will take place at 3 P.M. in the theatre of the College on Thursday, Nov. 3rd. We understand that the Associations of Fellows

and Members are now engaged in considering what resolutions shall be moved at this meeting, and the Association of Members is prepared to follow the guidance of the Fellows' Association instead of taking the independent action which has proved in the past to be disadvantageous to the common cause. We would strongly urge all Fellows and Members who have the good government of the College at heart to attend the meeting on the 3rd and support the resolutions which will then be submitted. The prospects of progress were never brighter, but it is necessary to remember the ancient maxim *festina lente*. Too great eagerness to advance is apt to engender opposition and to lead to disappointments, which delay the attainment of the objects in view. Those who intend to be present are referred to our special articles on the work of the past collegiate year, the calendar of the College, and the report of the Council of the College to be presented at the meeting.

#### WORRY, DRINK AND LUNACY.

It is no new thing to hear of the close connexion between indulgence in alcohol and the development of insanity. Accordingly we feel no surprise at a statement by Dr. Augustine Plaus that a large proportion of the cases of lunacy registered in Paris of late years are attributable to this form of excess. Far more significant is his observation that drunkenness has increased very markedly in the French capital. This effect is, of course, due to a variety of causes. Among these one is of particular interest from its bearing upon the neurotic aspect of the alcoholic dyscrasia. It is the pressure and worry of overwork, probably combined as usual in the like circumstances with irregular feeding and want of sleep. Though felt by all classes of workers, an important characteristic of its action as a cause of alcoholism is its increasing influence among those who labour with their brains. Artists, authors and especially journalists—a group of persons by no means usually given to excess—are enumerated as having succumbed to the subtle poison; and this result has, doubtless with truth, been attributed to the craving depression of mental fatigue. It is not difficult, indeed, to trace a connexion here, and we may accept it as a warning that forced labour is ever prone to become the natural parent of other and worse excesses. The best work, however hard, is always methodical enough to permit of timely rest and of regular nutrition, and the full recognition of this fact is a mere question of public utility which we hope to see more and more widely admitted in practice.

#### THE LONDON COUNTY COUNCIL AND GLANDERS.

WE recently alluded to a new Order which had been issued by the Board of Agriculture for the better controlling of glanders, and we commented with approval on the recognition by the Board of the identity of glanders and farcy and some other features in the management of the disease. We had to condemn, however, the continuation of the local authorities as the instruments through which the regulations were to be carried out, as the experience of years had amply demonstrated that they are incompetent to undertake such a function. The Public Control Committee of the London County Council has taken the same view, for at the meeting of the Council held on the 18th inst. it reported that the law in force in England with regard to the disease was much behind that of other countries; and, after showing how the disorder had increased in London and, that the Council had urged the Board of Agriculture to provide more effectual means for dealing with it and so putting an end to the fallacious measures already in force, it afterwards offered suggestions for the improvement of the new Order, a draft of which had been placed before it by the Board. These suggestions were: (1) the insertion of a

provision for compulsory notification of cases of disease by veterinary surgeons, following the principle already adopted in the case of infectious disease in man; (2) power to require the isolation and branding of suspected animals; (3) a certificate of freedom from contagious disease from a veterinary inspector should be necessary before horses could be submitted for public sale; (4) extension of the powers of inspection; (5) sanitary regulation and supervision of trade stables; and (6) compensation should not be payable when the animal slaughtered was diseased when it entered the district of the local authority ordering its slaughter. Of these suggestions the Board only incorporated in the Order that portion relating to branding and that having reference to the withholding of compensation. This the committee of the Council greatly regretted, as they attached much importance to the principle of compulsory notification, while the condition of London stables was in many cases notoriously bad and conducive to the spread of disease amongst horses. After duly considering the subject the committee came to the conclusion that a permissive order would be ineffectual as a means for stamping out glanders in England, and that to be effective the law must be uniformly administered throughout the country. They submitted the following recommendation to the Council: "That, having regard to the necessity for uniform action throughout the country for successfully dealing with glanders and farcy, and to the heavy expenditure that compensation without contribution from money voted by Parliament would impose upon the rates, and also to the fact that the Order does not include several provisions to which the committee attach great importance, the Council do not enforce the new provisions of the Glanders and Farcy Order, 1892, as to compulsory slaughter and compensation." This recommendation, we are pleased to know, was agreed to by the Council, which is to be heartily congratulated on the enlightened views it entertains as to the measures required for combating glanders. It is certainly in this instance much in advance of the Board of Agriculture, and it is to be hoped other county councils will follow its lead in this matter, and so compel the Board to apply to Parliament for further powers and no longer trifle and dally with such a damaging and dangerous disease.

#### THE SANITARY CONDITION OF SOUTHEND-ON-SEA.

In consequence of the continued prevalence of typhoid fever in this seaside resort it will be remembered that two years ago Dr. Thresh was called in by the local board to report upon the sanitary condition of the town, and if possible to ascertain the cause of the annual outbreaks of fever. The result of Dr. Thresh's investigations, which led him to consider the defects in the drainage and sewerage and the faulty method of sewage disposal as the most important factors in the causation of the disease, was not favourably received by the members of the board, and it required another sharp outbreak of typhoid fever to persuade them to carry out his chief suggestion—that an engineering expert should be called in to examine and report upon the whole sewerage system. Mr. Mansergh was commissioned to make the necessary examination and to advise the board. A few months ago he reported on the sewers, making recommendations for their extension and improvement, involving an outlay estimated at £10,000. He has now presented his second report dealing with the outfalls. He proposes to impound the sewage during certain portions of the day in two large tanks, allowing these to discharge during the falling tide only. The sewage from the lower portion of the town will have to be raised into one of the tanks by pumping. Two new sewer outfalls of 30 in. and 27 in. drain respectively are to be carried about one mile from the shore, the present outfalls for which they are substituted being utilised as storm

overflows. It is also proposed to place a 36 in. storm overflow immediately under the loading pier. Mr. Mansergh says he is aware that objections will be raised to its being placed in this position, but he is unable to suggest a better. The estimated cost of the intercepting sewers, tanks, pumping plant, outfall sewers &c. is £25,000, but this does not include any sum for land or easements. To carry out both the engineer's schemes in their entirety will therefore cost the town something like £40,000, a large sum certainly; but the first town council, which will in a few days be elected, cannot do better than boldly undertake the task and place the sanitary condition of the borough beyond reproach.

#### GRACEFUL GRATITUDE.

THE fitness of things does not often find more apt or more eloquent expression than that which reaches us through the medium of a recent kindly action of the well-known singer, Madame Nilssen. Many years ago, so the story runs, the voice, then in its childhood, which has held in silent admiration so many audiences, was often exposed to the wintry weather of a northern home. On one occasion an attack of acute laryngitis had nearly extinguished it for ever, but the care afforded by a neighbouring hospital preserved for later times its still unawakened melody. The assistance then given was not unacknowledged, and a sum of £1000 contributed towards the founding of a Parisian throat hospital attests to-day the gratitude of the illustrious singer and her sense of the priceless aid once rendered her by the medical profession. Her debt has in a great measure been already cancelled by the pleasure which her melodious notes have given to listening thousands, but there is nevertheless a singularly appropriate grace about this last expression of her feeling. Undoubtedly it has been rendered with excellent taste.

#### THE OPENING OF THE SCOTCH SCHOOLS.

THE custom prevailing in the University of Paris and elsewhere of the professor in each subject giving an introductory lecture at the opening of the session is carried out with a certain amount of uniformity in the Scottish universities. Reference was made to these addresses in our correspondent's letter last week, but it may not be amiss to glance through them once more, since, as may be expected from their authors, they are worthy of more than passing notice. It was pardonable, no doubt, for Professor Chiene at Edinburgh to point with pride to the growing numbers that flock annually to its medical faculty. He recalled the fact that thirty years ago the medical school of Edinburgh numbered only 400 students, and sent out 60 graduates a year, whereas at present the roll amounts to 2000, and over 200 are "capped" annually. It was characteristic of the genial and modest professor to couple with this legitimate pride an expression of humility as to whether he had done his duty to the vast numbers of pupils that had passed through his hands since he was chosen for the chair he holds. It is a thought which should be uppermost in the mind of every teacher earnestly seeking to fill his part adequately. In the course of his remarks Professor Chiene evoked great enthusiasm by his declaration that Lister had saved more lives by his labours than "had been lost by the greatest war waged between hostile nations." Professor Grainger Stewart dwelt on the prevalence of epidemic disease, and in particular upon influenza and cholera, asserting that there was not a shadow of doubt that the latter was caused by the comma bacillus, but admitting that the treatment of the disease had not progressed in the same proportion as the knowledge of its source and means of its prevention. Professor Fraser, as became the Dean of the Faculty, detailed to his hearers the numerous important changes that had been introduced into the curriculum, including provision for the

study of special subjects after graduation by those who desired to obtain a diploma of efficiency in one or other of the "specialties" which have become apparently a necessity of the age. This is, as it should be, the engrafting of a special branch upon a basis of sound general learning. He spoke with some warmth and sarcasm upon the requirement of the Commission that the subject of pathology should be taken after that of therapeutics, and stigmatised as "irrational" that the teaching and study of the treatment of disease should be undertaken before any knowledge had been acquired of the nature of the latter. We sympathise with Professor Fraser in his complaint, and feel sure that it will not be long before it is rectified; whilst at the same time we agree with Professor Greenfield, who, also speaking of the curriculum, pointed to the great advantage derived from postponing the pathological course until after those of anatomy and physiology had been completed. He also expressed the hope that a closer association would arise between the teaching of public health and that of pathology through bacteriology, which links them both together. At Glasgow the newly elected Professor of Surgery, Dr. Macewen, after alluding in befitting terms to his predecessor, dwelt upon the roll of illustrious names connected with the University of Glasgow, including William Hunter, whose fame had been overshadowed by that of his younger brother John, whom he encouraged and aided in every way to pursue the career that did so much for surgery and pathology. Professor Gairdner spoke well and wisely upon the future of therapeutics, the basis of which was, he said, being firmly laid by pharmacological research; but he deplored the waste of time and energy in imperfect observation and trial of remedies, and reiterated his conviction that systematic co-operation amongst practitioners would do an infinite service in establishing the value of measures of treatment. At St. Mungo's College Professor McVail, whose address is published on page 986, also dwelt upon the present position of medicine, particularly in regard to treatment, and sensibly referred to the extremely unsatisfactory way in which new remedies were brought to notice. He believed that we required to know more of the natural history of diseases, and that then there would be less indiscriminate drug-giving with possibly far more satisfactory results. Thus both Professor Gairdner and Professor McVail, representing as they do the highest position to which medicine has attained, see clearly the defects that are inherent in our art. It is not, as the shallow deem, because they are sceptical of the value of drugs in disease, but rather with the desire to possess a faith founded on knowledge and not on conjectures, that they seek to show us a more excellent way of establishing the truth of therapeutic laws. The work which is being done by such men as Lauder Brunton, H. C. Wood, Ringer, Fraser, Cash, Whitla and many others, is work in this direction. It will and must result in a simplification of our methods, and in a clearer insight into derangements which we term "disease," as well as into the means for rectifying them.

#### THE DEATH FROM PUERPERAL FEVER IN TYNEMOUTH WORKHOUSE.

An inquest was lately held at the Tynemouth Workhouse on the death of a single woman named Isabella Proud, from puerperal fever a few hours after admission. This much was clear and was certified by the resident medical officer, who added, however, that the death had been accelerated by improper removal, consequently the chief question at the inquest was the propriety of the removal of the patient, who was in a single room with a male lodger. The stench of the room was unbearable according to the relieving officer, who visited the case on the suggestion of the medical attendant, who proposed her removal to the workhouse. The relieving officer referred the case to the district medical officer, Mr.

Robson. In his absence, his father, Mr. James Robson, L.S.A. and J.P., saw the patient promptly. No one was attending to her, and the neighbours would not go into the house with him. The house was in a deplorable and offensive condition. Three women in the same house all refused to go into the room, being afraid. Mr. Robson saw there was no chance of life in such circumstances. He decided on her removal, and kindly undertook to accompany her. We entirely agree with the coroner that the removal was not improper at all, and, with a jurymen, that every credit was due to Mr. Robson for removing the woman. Recovery in a poisoned room was impossible, and even to die with a little attention is less pitiful than death would have been untended at home. Mr. Robson's humanity as well as medical wisdom redeem a sad incident from utter discredit. It is another instance of the medical man being almost the only friend of the infected and abandoned poor.

#### RELIGION v. CHARITY.

THE Dublin Corporation on Monday last, by 32 to 10 votes, refused to consider the annual grant of £250 to the Rotunda Lying-in Hospital, simply because the majority of its governors were not Roman Catholics. As a pronounced Nationalist, Mr. T. D. Sullivan, M.P.—to his credit, be it said—remarked that the wisest and noblest course the corporation could do would be to restore to the useful institution the grant which had been withheld for several years. It is acknowledged that the vast majority of the patients are Roman Catholics; neither is it denied that the subscriptions chiefly are derived from Protestants. As showing the one-sided action of the corporation, it may be mentioned that the following Roman Catholic institutions receive corporate grants as follows:—The Hospice for the Dying, £450; Mater Misericordiae Hospital, £500; St. Vincent's Hospital, £400; while the Adelaide Hospital, managed exclusively by Protestants, does not receive a single penny from the rates. The money of the ratepayers should be fairly allocated to all charitable institutions, or not at all.

#### THE "INDISCRIMINATE" SYSTEM OF THE INFECTIOUS HOSPITALS.

"WHETHER the patients be sent from the slums of St. Giles's or from Grosvenor-square the Asylums Board has no option whatever but to admit them." There is a universal admission of the fact that there is no let or hindrance to the reception of any person of any rank into the Asylums Board hospitals. And it may well be that a considerable proportion of the patients are of the class that could be well treated and isolated at home. The medical officer of health of St. Pancras is of opinion that as soon as the Foundling Hospital authorities found how easy it was for a wealthy private charitable institution to throw the cost of isolation, treatment, nursing and maintenance of their infectious sick on the ratepayers, they retraced the steps that they were taking for the treatment of their own cases within their own grounds. This point in the controversy between Mr. Littler and the Asylums Board is not the least interesting in the dispute, which is of high public importance. It is clearly public policy for sanitary authorities to provide easy and comfortable and effective treatment and isolation for the poor, but we must draw the line somewhere, unless we are to exclude the poor and to demoralise those who are able to take care of themselves. If the people in wealthy quarters are to be spared every cost and discomfort of infectious disease, we shall part with one wholesome protection against it—one of the strong motives for guarding against it. It is not only in regard to the question of admission to these hospitals that the rich have been demoralised by recent legislation, but also in provisions for throwing all the cost of disinfection

on the ratepayers as respects infected houses, rooms, articles &c. This sensitive consideration for the owner—even if perfectly able to do his own disinfection—at the cost of the ratepayer is a feature which distinguishes the Public Health Act of London from that of the provinces. True he is offered the choice and chance of doing it; but what tenant or landlord will undertake such duties when he knows that if he does not do so within twenty-four hours it will be all done for him at other people's expense? The legislation suggests the influence of property owners not only in London vestries but nearer the seat of Government, and is a part of that system which demoralises the individual and burdens the State. We are glad to notice that the Asylums' Manager does not undertake the defence of the system. He says the Managers are not to blame. Who is? In the name of the poor, for whom these hospitals and these provisions for disinfection are made, and in the name of the overburdened ratepayer, who has no right to bear the cost of the avoidable diseases of the rich, we press this question. We are only at the beginning of this system of making the State responsible for infectious diseases. Within limits it is certainly a right system, though it involves public vaccination, isolation, and all sorts of invasions of private liberty; but the limits are already becoming invisible, and we must not overdo it.

#### DISEASES OF ANIMALS.

A CONTEMPORARY states that cancer is reported to have made its appearance in one of the ponds of the Dunedin Acclimatisation Society of New Zealand. American brook trout only have been attacked, and none of the fish suffering from cancer have recovered. The statement that the disease has hitherto been unknown amongst fish is open to serious doubt. New growths are often found in animals, especially when they have been kept long in confinement. The animals which die in the Gardens of the Zoological Society are rarely of much use for dissection, as they so commonly suffer from tumours of the bones and viscera. Such diseases probably also occur in a state of nature, but would most likely lead to early death, the animal succumbing in the struggle for existence. In fish myxomatous and sarcomatous tumours have been seen. The fish *Platax arthriticus* has been known from the time of Hunter as possessing very commonly, if not always, in the adult dense bony tumours symmetrically disposed on many of its bones. Reptiles and birds appear to be the lower animals that are most subject to malignant sarcomatous growths.

#### INSANITARY ARTISANS' MODEL DWELLINGS.

It is not usual to find the owners of so-called model dwellings in the police-court to answer a charge of allowing their premises to remain in a condition dangerous to health. But the owners of the artisans' dwellings in Gun-street were recently summoned by the Southwark Vestry for allowing Nos. 1 and 2 Blocks in those buildings to be in such a state. The proceedings were taken at the Southwark Police-court under the Housing of the Working Classes Act of 1890. The sanitary inspector found the dust shoots in a bad state of repair, and with absent or deficient coverings; the soil-pipe ventilators were defective and only a few feet from the water of the uncovered cisterns on the roof, which contained vegetation from two to three inches in depth; on account of the absence of proper air inlets into the drain there was danger of the traps at the bottom of the soil pipe being forced by backward pressure of sewer gas; the waterclosets were unprovided with casements. Indeed the whole property was in a dilapidated and neglected condition. It was shown that these conditions were associated with a prevalence of enteric fever and bowel complaints in the dwellings. Dr. Waldo, the medical officer of health, gave evidence on behalf of the vestry; and some rebutting evidence was called to show that

the water was chemically pure, and that the basement drains were secure. Eventually the magistrate decided the case in favour of the prosecution, and made an order to close, which was to be suspended for a fortnight, to see whether some improvement could not be made in the meantime. At the adjourned hearing on the 13th inst. the health officer reported that he was substantially satisfied with what had been done, and the magistrate thereupon withdrew the order to close, but inflicted a penalty of £10 and £1 1s. costs in each case. We congratulate the Southwark Vestry and Dr. Waldo upon their vigour and on the success attending this important prosecution.

#### THERAPEUTICS IN THE WESTERN INFIRMARY, GLASGOW.

DR. CHARTERIS, Professor of Materia Medica and Therapeutics in the University of Glasgow, has not obtained the appointment of visiting physician to the Western Infirmary, in spite of the highest personal claims and the reasonableness of giving to a teacher of therapeutics the opportunity of illustrating the action of medicines in actual cases. We adhere to our view that such a professor ought to have such a clinical appointment, and that without it both the students and he are placed at a great disadvantage. The appointment was given to Dr. Samson Gemmell, lecturer on the practice of medicine at Anderson's College, Glasgow. Dr. Gemmell will of course make good use of his new appointment, but the defect of Professor Charteris's position remains.

#### MR. BRAXTON HICKS ON UNQUALIFIED ASSISTANTS.

MR. BRAXTON HICKS has made some very strong observations on the employment of unqualified assistants at an inquest on Robert Barnet, aged eighty-two, who had died of apoplexy. The friends sent for Mr. Graham, whose private residence is 56, Upper Kennington-lane, but whose surgery is at 123, Tyer-street. An unqualified assistant went, and administered brandy. Mr. Graham maintained that in using an unqualified assistant so, at a different residence even from his own, he was only doing what was the practice of the medical profession. He did not tell the jury what he ought to know, that it is a practice which has been severely condemned by the Medical Council and one for which many practitioners have been removed from the Register. It is lamentable to see a medical man not only doing that which is forbidden, but saying that it is the practice of the profession. The coroner intimated his intention to report this and every such case to the Medical Council.

#### AN AMENDED RABIES ORDER.

A NEW rabies order will come into effect on the 1st proximo, which, it is to be presumed, the Board of Agriculture expect will tend to allay apprehensions excited by the reports of outbreaks of the disease in different parts of the country and of persons dying from hydrophobia. The order only extends to England, Wales and Scotland, with the exception of the county and city of London, and its provisions are left to be carried out optionally by the local authorities. The order includes cattle, sheep, goats and swine, in addition to horses, asses, mules and dogs, and it sanctions compensation in those cases in which slaughter of animals is found to be necessary. In respect to dogs, every local authority is empowered to seize those which have wandered into its district, subject to the usual provisions as to the duration of detention, giving notice to owners, recovery of penalties for infringement of the order and repayment to the authority of reasonable expenses incurred. If dogs are not claimed within three days they may be destroyed; if the owner has had notice, slaughter may take place within two days. Every person who has possession or charge of any rabid animal

must immediately give notice to a constable, who is to report to the local inspector and to the Director of the Veterinary Department of the Board of Agriculture. Inspectors have authority to resort to prompt action when they suspect the existence of rabies; and the local authority may, if it is considered necessary, warn the public by placard of the existence of the disease at any particular place. Local authorities may issue any other regulations they may deem requisite for the muzzling of dogs or keeping them in control; also for prohibiting the movement of animals affected with rabies, for cleansing places where they have been, for disposal of carcasses, and for the production of licences and the names and addresses of owners.

#### "SCHOOLS" V. "HOSPITALS."

At the opening of the medical session of St. Vincent's Hospital, Dublin, the lecturer, Dr. McHugh, propounded the suggestion of the advisability of instituting systematic courses of instruction in the wards of hospitals to replace in great measure that which is still carried on in the old scholastic style. He urged also upon all students not to defer acquaintance with clinical work until they had perfected themselves in anatomy and physiology, but maintained that clinical instruction should go on *pari passu* with scientific studies, the growth of which was tending to draw students away from the source of their purely professional knowledge. We fear rather that the latter suggestion would not work well in practice, but we cordially sympathise with Dr. McHugh's desire to make clinical teaching more thorough and systematic. Dr. Myles, who proposed a vote of thanks to the lecturer, feared that the proposal to transfer the teaching of medicine and surgery from school to hospital would not be acceptable, since it would tend to lower the general average of teaching power now concentrated in the few selected for their special qualifications as teachers. Mr. Tobin, however, who seconded the motion, contrasted the advantages of bedside instruction with that given in the lecture theatre.

#### LONDON SLAUGHTER-HOUSES.

LAST week the Public Health Committee of the London County Council sat as the licensing authority for London slaughter-houses and cowsheds. Licences for these premises are granted annually, and there is thus opportunity for the committee to deprive any person of his licence who has failed to comply with their requirements. During the last year the London County Council has adopted new by-laws for slaughter-houses, and, as a result, a number of butchers have been unwilling, or found it impossible, to meet the demands of these by-laws and have not made application for the renewal of their licences; the butchers, in fact, have learnt that they can obtain their meat supplies at the Metropolitan Meat Market, and that fresh meat is procurable from Scotland or other parts of the country, and again, the large quantities of dead meat which come from abroad, especially the colonies, have rendered less necessary the killing of animals in London. The *St. James's Gazette* contains this week an interesting article on the subject of meat-supplies to London, in which it is shown that farmers are increasingly adopting the practice of killing their cattle and sending the carcasses to the meat salesmen. It is admitted, however, that there is one serious objection to a general system of farm slaughter-houses—viz., that it does not give the opportunity for meat inspection which is thought to be necessary. This question of meat inspection is one which has attained less prominence in England than in many continental countries, but it cannot be long before communities will have to consider whether they must adopt some method which will prevent the sale of unwholesome meat. If bovine tuberculosis be alone considered there is already reason for the adoption of a system to ensure that the purchaser is made

aware that the flesh he is buying is not that of a wholly sound animal. It is impossible for meat to be properly inspected in London while animals are killed in some 600 different places. The suggestion made in the *St. James's Gazette* deserves consideration, viz., that public slaughter-houses should be provided in different parts of the country—at Cambridge, for instance, not far from the Eastern counties' farms—where animals could be killed without undergoing the fatigue and terrors incident upon their conveyance to London.

#### THE HEALTH OF WINDSOR.

WE note with satisfaction that during the last six months the death-rate of the borough of Windsor has been as low as 10·8 per 1000, and that during the month of September there has been no death within the borough from diarrhoea or any of the zymotic diseases. It is now some years since we felt it our duty to publish certain statements concerning the sanitary condition of the Royal borough—statements which were in the first instance denied and subsequently were the cause of an inquiry by the Local Government Board. The report of the inspector entrusted with this duty vindicated the accuracy of our statements; it is therefore with the more satisfaction that we are able to return to the subject and to give publicity to the low death-rate of which Windsor can now boast.

#### PERFECT COMBUSTION AND SMOKE PREVENTION.

THE system of firing which formed the subject of an investigation by THE LANCET Analytical Sanitary Commission in the early part of the year, a full account of which appeared in our issue of March 5th, 1892, was the subject of a demonstration on Tuesday last at 100, Shaftesbury-avenue. Amongst those present were Sir Frederick Abel, Mr. Alderman Hammond, J.P., Sir Guyer Hunter, Sir Nathaniel Barnaby, Sir E. Reed, Professor W. H. Robinson, Professor W. Corfield, Mr. H. S. Foster, M.P., Mr. Ernest Spencer, M.P., and the Mayor of Bradford. In addition to the ordinary kitchen range, which was the subject of our report, the same principle has now been successfully applied to fires for dwelling-rooms, steam boilers and destructors. In view of the comprehensive account already alluded to it is hardly necessary to describe the system further. Suffice it to say that the engineers and other experts present expressed their entire approval of the device. The stove burns the commonest kinds of coal, produces little or no soot, and is so constructed that the smoke first produced is forced to pass through an incandescent mass by which the temperature necessary for its complete destruction or combustion is attained.

#### INSANITARY HOUSES.

WE commented last week with some satisfaction on a heavy penalty imposed upon the owner of a house who had neglected to obey the order of a vestry requiring him to put it into a proper sanitary state of repair. We may now refer to the imposition of a penalty of £21 14s. upon the owner of six cottages in White-square, Clapham, for a similar offence. We are convinced that the punishment awarded by the magistrate in these cases will have a salutary influence upon the owners of other insanitary property. We have also before us the fact that the owner of a house in Harleyford-road, Kennington Oval, was fined for allowing the premises to be in a state dangerous to health. He had been unable to recover possession owing to a room in the house being occupied by a woman and her two children who would pay no rent, and who refused to go out. The windows and doors had been removed and eventually the sanitary authority had to intervene. An order was made for the closing of the house. Again, on Saturday last

Mr. Carttar held an inquest on the body of a boy who died at Diiston-road, Rotherhithe. He had been living in a house in St. Helena-road with his father and eight other members of the family, but, having got into arrears with their rent, the landlord, after warning the father, had taken off the doors and windows in order to force him to leave the premises, and as a result the deceased died from chill. A sadder story can scarcely be told. It is obvious if rent cannot be paid that the landlord is entitled to possession, but the law must be very faulty if there is no better way of evicting the tenant than the course adopted in the last two cases. It may be hoped that this occurrence will not pass unnoticed and that its repetition will be rendered impossible.

#### OVERCROWDING OF THE PROFESSION IN NAPLES.

ACCORDING to some statistics collected by the *Riforma Medica* the number of medical men in Italy is steadily and rapidly increasing, and the overcrowding is especially great in Naples, where there is one medical practitioner to every 513 inhabitants. Medical incomes are consequently diminishing, and are shown by the income-tax returns to be distinctly inferior to incomes earned by members of other liberal professions, as lawyers and engineers. The outlook is, according to the *Riforma Medica*, a very gloomy one for medical men, and it does not seem possible to doubt that their position will soon become decidedly worse than it is now.

#### THE NEW ENTRIES AT THE MEDICAL SCHOOLS.

IT is premature to draw conclusions as to the numbers commencing the study of medicine in the present year. So far as our returns go, in spite of the lengthened curriculum imposed by regulation of the General Medical Council, these numbers show an increase. Our readers may remember that last year there was a very considerable rise in the number of medical students registered during the year, a rush which was naturally attributed to the desire to get the advantage of the older and shorter curriculum. If the Scotch and Irish and other returns not yet to hand should show, as our present returns seem to do, a further rise, we shall have to seek another explanation. One thing seems clear: that that calamity once feared by Lord Playfair is not likely to be realised—a dearth in the supply of medical men.

#### TYPHOID FEVER ON SEWAGE FARMS.

IT is alleged that two boys, each aged sixteen years, have died of typhoid fever, contracted from working on the sewage farm of the Manchester Corporation at Carrington. This is a very serious allegation against the management of the farm, which will doubtless be fully met by the corporation. For the negative evidence on this point of the production of enteric fever from sewage farm effluvia is so strong, from the history of the Croydon, Edinburgh, and other farms, that, if the facts be true, a strong presumption against the farm is raised. In the meantime, another question crops up, as to whether boys of such age should be employed at all on a sewage farm; and whether, in view of enteric sewage being often dealt with on them, it would not be better to employ men of middle age for the purpose.

#### DINNER TO SIR WALTER FOSTER, M.P.

A DINNER, presided over by Dr. Withers Moore, President of the Council of the British Medical Association, and attended by a large gathering of leading members of the medical profession, was given on Wednesday evening last at the Hôtel Métropole to Sir Walter Foster, M.P., in honour of his appointment as Parliamentary Secretary to the Local Government Board. The chairman, in proposing Sir Walter Foster's health, congratulated him upon being the first member of the medical profession to be appointed

to a post in an English Government. In replying, Sir Walter Foster said he had held almost every office in the British Medical Association, and that it was in the Association that he received his chief training for public work. He believed that in the great problems with which the Government would have in the future to deal the coöperation of medical men as authorities on the laws of public health would be more and more required. Mr. H. H. Fowler, President of the Local Government Board, whose health was most enthusiastically drunk, referred to the number of medical men with whom that department had become officially associated as being between 4000 and 5000; that department had recognised the fact that the most valuable part of a man's property was his health, and the statistics of recent years showed a remarkable diminution in the death-rate.

#### BUCHANAN PRESENTATION FUND.

WE understand that a final meeting of the committee of the above fund is to be held on Thursday, November 3rd, at the residence of the treasurer, Dr. Bristowe. Any intending contributors to the fund should forward their subscriptions at once to one of the secretaries—Dr. W. H. Hamer, 73, Dartmouth-park-hill, N.; Dr. J. C. Thresh, The Limes, Chelmsford, Essex.

#### ALLEGATIONS AGAINST A MEDICAL OFFICER.

SERIOUS charges of neglect of duty have been made against one of the medical officers of the Birkenhead Union by certain of the guardians. He is accused of having neglected three cases that he was called upon to attend. The inquiry has been adjourned, when it is hoped that the officer will be able to exonerate himself from the charges made against him. In the meantime it would be premature to comment upon the case.

#### TOUCH AND TEMPERATURE SENSE.

AN interesting case, illustrating peculiarities in sensory perception, is recorded by Cavazzani and briefly mentioned in the *Neurologisches Centralblatt*. It is that of a patient whose median and ulnar nerves had been injured and then sutured. On testing the sensibility after this it was found that in certain areas where the temperature sense was retained there was no sensibility to ordinary impressions, and in other areas the converse was the case, thus giving support to Goldscheider's idea that the end-organs and conducting paths are different for the different kinds of sensibility. As, too, there were areas where only cold was perceived, while tactile and thermal impressions were not felt, it seems as if there were separate paths for heat and cold. It was also curious that a trial made when the patient was about to leave the hospital at a time when he was somewhat excited should have furnished results not quite the same as those obtained before—a change which is ascribed to the altered condition of the nervous centres due to the excitement.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Berlin*.—The Second Anatomical Institute is now finished. It is under the direction of Professor Hertwig and will be devoted mainly to microscopical anatomy and development. Dr. van Ackeron has left the Second Medical Clinic for Chicago and Dr. Vogel has been appointed to his post.

*Breslau*.—Dr. Beerwald has been appointed Oberarzt of the hospital in place of Professor Rosenbach, who has resigned.

*Innsbruck*.—Dr. Juffinger of Vienna has been appointed Honorary Lecturer in Laryngology and Rhinology.

*Moscow*.—Dr. Krinkoff has been appointed Extraordinary Professor of Ophthalmology.

*Tomsk*.—Dr. Barteneff of Kharkoff has been appointed Extraordinary Professor of Children's Diseases.

THE HODGKINS donation of £20,000 to the Royal Institution of Great Britain is, we understand, unfettered by any narrow restrictions. The utmost latitude in applying the interest accruing from it is left to the managers of the Institution, who will doubtless employ it in promoting those researches into the properties of liquid oxygen which have recently reflected renewed lustre on the laboratories in Albemarle-street. Impressed by the great scientific interest and practical importance of these researches the Goldsmiths' Company has contributed £1000 towards the expenses connected with them.

A LIVERY BANQUET was given by the Fishmongers' Company in their hall on Wednesday to a large number of the members of the medical profession. Among the guests were Sir J. Paget, Sir W. S. Savory, Surgeon-General Sir J. Fayer, Sir E. H. Sieveking, Sir J. Crichton Browne, Sir T. S. Wells, Surgeon-General Sir W. G. Hunter, Sir W. Roberts, Sir Dyce Duckworth, Sir G. Johnson and Mr. T. Bryant (President of the Royal College of Surgeons).

A PUBLIC BANQUET will be given to Alderman Joseph Ewart, M.D., Mayor of Brighton, on his formal re-election on Nov. 9th, in recognition of the able manner in which he has performed the responsible duties of his office during the past year.

AMONG the witnesses who gave evidence before the Royal Commission on Vaccination, which met for the first time after the recess on Wednesday last, were Dr. J. C. McVail and Mr. H. H. Sturge, M.R.C.S.

THE Doncaster Infirmary has received £25 from the Duke of Portland out of money charged to visitors to the Welbeck grounds.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### *The Work of the Past Collegiate Year.*

THE following summary of the work of the past Collegiate year (1891-92) at the Royal College of Surgeons is arranged under the headings of the Secretary's Report and the Report from the Council to the Meeting of Fellows and Members which is to be held on Thursday, Nov. 3rd, 1892, at 3 P.M.

### *Laboratories on the Embankment.*

The Council of the College approved in November the decisions of the Laboratories Committee that a short series of lectures should be given during the month of December, and that papers by workers in the laboratories should be allowed to appear in scientific journals with the approval of the Committee. During the year about forty-two applications were made for permission to work in the laboratories, and of these thirty were approved by the committee. Lectures were delivered by Dr. Sims Woodhead (the Director), Dr. Ruffer, and Dr. Wright in the theatre at the Examination Hall.

### *The Committee of Management and the Curriculum of Study.*

On June 17th, 1891, Dr. Mitchell Bruce submitted to the Royal College of Physicians, on behalf of the examiners in *materia medica*, a list of drugs contained in the Addendum to the British Pharmacopoeia, which they thought should be added to the schedule for the First Examination, Part II.; and the committee, having had the letter referred to it by the Royal College of Physicians on July 30th last for consideration and report, recommended that in view of the approaching extension of the curriculum of professional study from four to five years, and the consequent alteration and rearrangement of the subject, it was undesirable to make any addition to the schedule of drugs in use at the present time.

On Nov. 2nd, 1891, the committee considered the following rule relating to the conditions of admission to examination for diplomas in State Medicine adopted by the General Medical

Council on Nov. 25th, 1890, and referred to the committee for consideration and report by the Royal College of Physicians and by the Royal College of Surgeons on June 25th last:— "Every candidate shall have produced evidence that during a period of six months after obtaining a registrable qualification he either has practically studied the duties of out-door sanitary work under the medical officer of health of a county or large urban district, or else has himself held appointment as medical officer of health under conditions not requiring the possession of a special Sanitary diploma"—and recommended that such regulation be added to those at present in force for the diploma of Health for the two Royal Colleges. This recommendation was adopted by the Colleges. The scheme for the extension to five years of the curriculum of professional education for the diplomas of the two Colleges adopted last year by the two Colleges has undergone revision and has been published in THE LANCET.

### *New University for London.*

The action of the Council in regard to the proposed Gresham University was described in THE LANCET of Nov. 7th, 1891.

### *Army Medical Examinations.*

On Jan. 14th, 1892, a committee consisting of Sir William S. Savory, Bart., Sir William MacCormac and Mr. N. C. Macnamara, with the President and Vice-Presidents, was appointed to consider and report to the Council on a letter addressed to the President from Sir Ralph Thompson, K.C.B., requesting, by direction of the Secretary of State for War, to be favoured with the views of the President on the suggestions for the mode of conducting the competitive examinations for admission to the medical staff of the army, especially with regard to the following suggestions—viz. (a) That the examinations should be conducted by the joint board of the Royal Colleges of Physicians and Surgeons which examines candidates for entrance into the civil branch of the profession; or (b) that the appointment of examiners should be made on each occasion by the Royal Colleges.

A similar letter was received by the Royal College of Physicians, and a committee was also appointed by that College to consider the matter. The two committees having held separate meetings, and the result of their deliberations proving to be practically similar, subsequently met together and agreed upon a joint report to the two Colleges, in pursuance of which a reply was sent to the Secretary of State for War stating that the two Royal Colleges were willing to undertake the conduct of the examinations for admission to the Medical Department of the army subject to the following conditions—viz.: 1. That the examinations shall be under the control and management of a committee, to consist of representatives of the War Office, of the Royal College of Physicians and of the Royal College of Surgeons. 2. That the examiners shall be nominated by the committee and appointed for a definite period by the two Royal Colleges. 3. That every candidate shall be examined in each subject by two examiners in conjunction.

In the event of these conditions being accepted by the Secretary of State for War the Colleges further recommended that the committee referred to in condition No 1 should be at once appointed; and that it should be referred to such committee to draw up a scheme of examination for consideration by the War Office and by the Royal Colleges. No further communication has been received from the War Office on this subject.

### *Annual Meeting of Fellows and Members.—Steele v. Savory.—Further Advantages to Fellows.*

These topics have been fully dealt with in the pages of THE LANCET.

### *Miscellaneous Topics.*

Addresses of condolence on the occasion of the death of the Duke of Clarence and Avondale from the President, Vice-President and Council were drawn up and forwarded to the proper authorities for presentation to the Queen and to their Royal Highnesses the Prince and Princess of Wales. A vote of condolence with Mrs. John Wood and family was passed on Jan. 14th, when the decease of Mr. John Wood, F.R.S., was reported. A similar vote of condolence with Mrs. Hill and family was passed on the decease of Mr. Berkeley Hill. The death of Mr. Charles Hawkins elicited a unanimous expression of regret, which was sent to his sister, Miss Hawkins. The penalty of removal from the list of Members was inflicted on Caleb Charles Whiteford, convicted of a criminal offence, and on Michael Perry, of Sydney, N.S.W., for continuing to issue his unprofessional

advertisements, notwithstanding his statutory declaration that he would discontinue them.

At the quarterly meeting of the Council in July Mr. Howard Marsh and Mr. John Tweedy were admitted members of the Council. Mr. Thomas Bryant was re-elected President, and Mr. Arthur Durham and Mr. Christopher Heath were elected Vice-Presidents for the ensuing year.

#### *Library.*

Considerable progress has been made with the new catalogue; as far as finished it is available for use by readers. The library was open on 263 days during the past year, as against 277 in the previous year; the extra closing was rendered necessary by the drainage works carried out during the summer. The number of readers for the year was 9787.

*Fellows and Members.—Examinations.—Board of Examiners.*

*Finances.—Income and Expenditure of the College.*

Full information will be found in the Special Article, Calendar of the Royal College of Surgeons.

The report of the Council brings into prominence the following facts with reference to finance.

#### *Income.*

The total income of the College for the past year exceeds that of the previous year by £438. This difference is due to the increase in the amount of the fees received for the several examinations, the total gain under this head being £881 17s. The dental examination fees have increased nearly £100, but the gain is chiefly made on the examinations for the diploma of Member. In the case of the examinations for the Fellowship there is, however, a decrease of £171 5s. In most other cases the receipts are slightly smaller. The incidental receipts both at the College and from the Combined Examining Board are rather smaller, and the receipts from house property are also less, owing to a change of tenants and readjustment of rents at No. 37, Lincoln's-inn-fields. The income from dividends and stocks and shares has been reduced to the extent of £228 5s. 6d. by the sale of stock.

#### *Expenditure.*

The total expenditure, exclusive of that on buildings, is within a few pounds the same as that of last year, and on being deducted from the total income leaves a balance of £450. This sum would, however, have been considerably larger if it had not been for the unusual amount of nearly £2000 disbursed this year under the head of Extraordinary Expenditure, including the cost of a conversatione, furniture and fittings, and part of the outlay on extensive alterations to the drainage of the College buildings. With regard to the standing or ordinary expenses there is no very marked difference from those of the previous year. The total sum expended on examiners' fees is, of course, larger in proportion to the increase in the amount received from examination fees. The expenditure at the Examination Hall is almost the same, while that for the laboratories is £300 less—a smaller amount, as was anticipated, having been spent on furniture and fittings. The expenditure on the laboratories is, however, still £100 in excess of the sum estimated before their institution as the amount of probable annual expenditure. In the general working expenses of the College there is an increase of £650, chiefly due to alterations and repairs in the museums and at 44, Lincoln's-inn-fields. The special expenses of the museum are about £300 heavier this year, this being due to payments for catalogues, and the expenses of the library remain about the same. The extraordinary expenditure on buildings &c. amounts to £10,209, on the extension of the College premises, and to £1000 on the extension of the Examination Hall buildings, and to meet this it has been necessary to sell out £12,000 stock. The contracts for these works have now been completed, and the College has no further liability in this respect.

#### *Probable Income and Expenditure.*

Assuming that the examination fees remain about the same as in the last year, the income of the College will probably be about £200 less, owing to the loss of dividends by the sale of stock. On the other hand, the total expenditure should also be about £500 less, as the expenditure on fees to the Court of Examiners, on alterations and repairs, on law expenses and on museum catalogues, will probably be smaller than in the previous year. This would leave a balance of £750. As in the last year, there will be heavy expenses beyond the standing or ordinary expenses, the chief of these being a further payment of about £1300 on the drainage

works, and this consequently makes the balance on the revenue account appear somewhat small.

#### *Obituary.*

The list of Fellows and Members contained in the report of the Council whose deaths have been reported as having taken place during the year includes the names of 44 Fellows and 298 Members.

#### THE REPORT OF THE COUNCIL.

The report of the Council of the Royal College of Surgeons of England for the collegiate year 1891-92, which has just been issued and will be presented to the annual meeting of Fellows and Members on Nov. 3rd, follows the lines of the report last year. The matter is arranged under the sixteen headings following: the Curriculum of Study, New University for London, Army Medical Examinations, Annual Meeting of Fellows and Members, Steele v. Savory, Further Advantages to Fellows, Removal of Members, Elections, Museum, Library, Finance, the Laboratories on the Embankment, Lectures, Returns of the Results of Professional Examinations, Statement of Receipts and Expenditure, the three last being contained in the Appendix. The most notable improvement in this report is the substitution of an abstract of each course of lectures delivered at the College, supplied by the lecturer himself, for the stereotyped syllabus, and the most notable difference between the secretary's report in the Calendar and the Council's report is that in the former there is a full shorthand report of the trial Steele v. Savory, whilst in the latter only Mr. Justice Romer's judgment is inserted. It may be interesting to state that the total costs of the College in the action amounted to £1216 13s. 4d., and in Tait v. Savory to £48 3s. 2d. The sum of £43 14s. 4d. was received from the plaintiff in Tait v. Savory, and the taxing master's certificate for the taxed costs in Steele v. Savory amounting in all to £722 14s. 4d. was obtained. The sum of £360 has been paid on account of the taxed costs in Steele v. Savory, and promissory notes have been given by Dr. Danford Thomas for the balance of the taxed costs payable at four and eight months from June 2nd, 1892. The benefit to the cause of constitutional progress resulting from the settlement of the action is exemplified in the section relating to further advantages to Fellows. The Fellows and Members have gained a common room at the College, and the principle of calling the Fellows together separately from the Members for consultative purposes has been established. The first meeting of the Fellows was held on July 7th, and the report naïvely states: "No special subjects were announced for consideration, the object of the meeting being to afford the Fellows an opportunity of expressing their views on any points they might wish to bring forward." This statement is remarkable, because when notices of the meeting were sent out no kind of intimation of this object was vouchsafed. The Fellows were merely invited to meet the Council, and, as occurred at the celebrated meeting at Ephesus, the most part of those assembled knew not wherefore they were come together. The idea of withholding the statement of the object of the meeting in the summons and describing it some months later in the Council's report is singularly collegiate.

Notwithstanding the inclination which has been shown by the Council to advance, it must be obvious to all that, if any substantial concessions are to be obtained, the Fellows and Members will be obliged to continue to press upon the Council those points of reform in which they may be unitedly or severally interested; and it is for the Association of Fellows and the Association of Members to take care that the present opportunity shall be properly utilised. It ought not to be forgotten that the annual general meeting of Fellows and Members has narrowly escaped abolition during the past year owing to the effervescence of reformers last November, when the near approach of the action Steele v. Savory and too sanguine anticipations of victory disturbed the balance of some of the more eager disputants. That no similar error will be committed this year we are well assured, and the danger is that reaction will produce an apathy and want of life and interest in the proceedings which may be cited as evidence of the inutility of the annual general meeting. The finances of the College do not wear an altogether satisfactory aspect. There is, it is true, a balance of £450 in respect of revenue over expenditure, but the extraordinary expenditure of £11,209 for extension of the College premises and the Examination Hall buildings has necessitated a sale of £12,000 worth of stock. The contracts for these works have now been completed, and the College has no further liability in that respect. There will be, however, a

further payment of about £1300 to be made for drainage works, and it is very doubtful whether the possible balance of £750 which is expected next year will be realised. Owing to the loss of dividends by the sale of stock the income will be so far less by £200, and just as it is the unexpected which happens, so extraordinary expenditure may ordinarily be looked for. In our article on the finances of the College published in February we contended that the present expenditure at the College ought to be reduced so as to ensure a margin sufficient to admit of a substantial annual investment for the purpose of bringing up the fixed income to a level with necessary expenditure. If this were done the College would be less dependent upon the fluctuating receipts derived from examinations, and the finances would be placed in a far healthier condition.

## INTERNATIONAL MONUMENT TO SEMMELWEIS.

A SPECIAL MEETING of the profession in aid of the movement now on foot to erect an international memorial to Dr. Ignatius Philippus Semmelweis in his native city of Budapest took place in the library of the Royal College of Physicians on the afternoon of the 24th inst., Sir Andrew Clark, Bart., President of the College, in the chair. Dr. Cullingworth, one of the honorary secretaries, read a number of letters expressing sympathy with the object of the meeting, and regretting inability to be present. These included, amongst others, messages from Sir James Paget, Sir Joseph Lister, Sir Richard Quain, Professor Simpson of Edinburgh, and Dr. J. W. Byers of Belfast. The meeting was open to all the members of the profession, and amongst those present were Sir Spencer Wells, Dr. Routh (who first brought Semmelweis's discoveries before the profession in this country), Dr. Duka (a fellow-countryman of Semmelweis), Dr. Watt Black, President of the Obstetrical Society, &c.

Sir ANDREW CLARK, in taking the chair, said: The story of the circumstances which have brought us together this afternoon is, I think, one of the most interesting and most instructive and one of the most touching and most inspiring that I have ever read. I venture to think that perhaps nowhere else than here, where traditions of self-sacrifice in the service of truth abound, could such a history be better told. I presume that all here are so well acquainted with Semmelweis's history that it is unnecessary for me to enter upon it now, or to occupy your time in dwelling on the points in that life story which have made it famous in the whole history of science. Instead of that I shall ask Sir Spencer Wells to move the first resolution. He will have the opportunity of recalling to the minds of those present at this meeting those points in that history which make it so exemplary to us all.

In proposing the first resolution, "That the project of erecting a monument to Semmelweis by international subscription deserves the support of the medical profession of Great Britain and Ireland," Sir SPENCER WELLS said: This movement will derive importance from being held here. I need hardly ask why it deserves our support, because the work done by Semmelweis is honourable to us all, to the whole profession, not only in his country but in our own and in all the world; because all have a pleasure in giving credit to all true workers who have done good to mankind, who have studied the causes of disease and sought out how diseases could be prevented and human life could be saved. Semmelweis has done this, and the influence he has exerted is honourable to us all and of immense benefit to our patients. He deserves a monument, and we honour ourselves by supporting the project of his fellow-countrymen. After fifty years—when his chief work was done—he has been partly forgotten and never sufficiently known or appreciated here. In 1849 Dr. Routh first brought before the profession the work of Semmelweis by reading a paper to the Royal Medical and Chirurgical Society on Endemic Puerperal Fever in Vienna. Semmelweis demonstrated that puerperal fever was due to inoculation, to the direct application of poisonous matter to the vagina, and that the poison—such as organic matter below the nails or in the epidermis on the examining fingers of the students and doctors who had been engaged in anatomical or pathological investigations—so communicated was the cause of the malady,

and that women attended by those operators were attacked, whilst those patients escaped who were attended by midwives not so occupied.

Dr. DUKA, in seconding the resolution, said: I feel deeply honoured by having been charged to second the resolution so ably and most kindly proposed by Sir Spencer Wells. I am unable to speak as I should wish on the merits of the man whose memory his professional brethren of a later generation are here assembled to honour, nor of the details of his work which gave him most justly the appellation of the "Father of Antiseptic Midwifery;" his struggles in the service of humanity and the touching incidents of his melancholy end at the age of forty-seven I refrain from dwelling upon. Semmelweis was a countryman of mine, and as I have been for some months past in correspondence on the subject with our professional brethren in Hungary I am enabled to give some account of the origin of the movement, the object of which is to erect a statue to Semmelweis by international subscription at Budapest. Semmelweis died in 1865 at Vienna, and was buried there a quarter of a century after—namely, in April, 1890—at the instance of relatives. His remains were transferred to Budapest and reinterred in a spot specially designated by the authorities of his native city. The solemn rite was performed amid manifestations of universal sympathy and respect. Following that solemn occasion the idea of a permanent public memorial was mooted, and in consequence of it the professors of the University conjointly, with certain members of the Medical Society of Budapest, formed a committee to take the necessary steps in the matter. Thus the Central Committee of the Semmelweis International Monument was constituted, with Dr. Késmarszky, professor of gynecology, as its president. From that body emanated the letter addressed to Sir Spencer Wells, who, with his usual kindness and devotion, aided by the *ad interim* committee, and particularly by Drs. Cullingworth and Boxall, successfully paved the way for this meeting of the profession under the distinguished chairmanship of the President of the Royal College of Physicians. I am commissioned by the Central Committee at Budapest to express deeply felt gratitude for the countenance and patronage given to this movement in this country. The Committee are issuing special invitations to the profession throughout the civilised world, except to the United Kingdom, India and our colonies, which are to be left to be dealt with by the British Committee. They furthermore hope that when the next International Congress of Hygiene meets at Budapest in 1894 they will be in a position to submit to the subscribers at large the final plans of the undertaking. The Central Committee hope also that they may look with confidence to their professional brethren in the United Kingdom for sympathy and substantial support, knowing their humane and generous feelings. If there should be any who are insufficiently informed on the subject as to the great work Semmelweis has done for suffering humanity, I venture to submit the testimony of two authorities whose judgment no one can call in question. Sir Andrew Clark, in a letter to me in 1888, wrote, in acknowledging my pamphlet on Semmelweis: "The story is at once interesting, instructive and touching, and you have told it with grace and sympathy. It seems inexpressibly sad that one who rendered so great a service to mankind was not spared to find his services acknowledged and his work crowned with a great and growing success." The late Dr. Matthews Duncan, in the same connexion, said: "Thanks for your little book to the glory of Semmelweis. I have lived through it all, and never doubted his great merits. It will do good to spread his name." I beg formally to second the resolution.

Dr. ROUTH, in supporting the resolution, said that he had had the honour of communicating to his brethren in this country the first fruits of Semmelweis's labours. In looking back to his student days he remembered the man, full of intelligence, full of intense sympathy, never allowing anything to interfere with his duties.

Sir ANDREW CLARK, before putting the resolution to the meeting, remarked that there were three qualities about the man himself which had not been noted. First, there was that great quality of scientific instinct; that remarkable quality, secondly, of moral heroism; and thirdly, the question of his martyrdom, for a true martyrdom it was. As to his scientific instinct, he made the resolution to discover the cause of childbed fever or die. He took up theory after theory, and, in spite of all the difficulties in his story, he continued his work with a patience, a self-denial

and self-effacement rarely seen. It touches one not only on account of the perseverance with which he followed his scientific instinct, but also because of the success by which, through the accident of his friend Kolletschka's death, it was crowned. The question and details of the friend's death he spent weeks and months in studying, and thus made his first discovery and bit by bit got out the light until it flooded him entirely. He discovered that it was dead matter carried under the nails of the students; but this did not explain the whole of the questions. He made the second discovery, that it was living matter in a state of septic change. Still he was not satisfied, but by further investigation he came to the conclusion of the autogenetic infection. There are few such parallels in the history of science. In regard to his tremendous moral heroism, in spite of every conceivable difficulty, in positions of misrepresentation, in spite of persecution, he continued his labours until crowned with a full clearing up of the difficulties. As to his martyrdom, there is not such a history. The persecution to which he was exposed in the later years of his stay in Vienna, his being hounded out of Vienna and settling in Budapest, and his premature end in loss of reason, form indeed a sad story and one of the highest examples that can be presented. I most warmly concur in the movement and feel constrained to do everything in my power to assist its promotion.

The resolution was carried unanimously.

The second resolution, "That India and the English-speaking colonies be invited to coöperate with this country," was proposed by Dr. PRIESTLEY. In doing so he said that no better illustration of the saying that the good a man does lives after him could be seen than in the result of the discoveries of Semmelweis.

Dr. GLOVER had the greatest possible pleasure in seconding the resolution and taking part in such a movement. He could imagine nothing more fit than the use of the College of Physicians for the purpose of the meeting, and nothing more worthy of the President's power of exposition than the careful definition of Semmelweis's work and his high eulogy of it. What could be more meritorious than a discovery, however simple, that reduced so hugely the mortality and the sufferings of lying-in women? Next to the great human interest of the question was its deep professional interest, especially to general practitioners, who were brought into closest touch with those for whose benefit Semmelweis had laboured. By demonstrating the way in which the practitioner can avoid the risk of conveying puerperal poisons Semmelweis and his antiseptic followers had added immensely to the happiness of general practitioners. He sincerely trusted that the great body of practitioners whom he had the honour to represent would do their part in raising a lasting, if a late, monument to the genius and the merit of the much decried Viennese professor; and also that the committee would be able to devise some means of appealing effectually to the practitioners in India and the colonies.

Dr. WATT BLACK proposed the third resolution—viz.: "That the maximum subscription be one guinea." Hitherto, he said, there had been unanimity in the meeting, but in reference to the subscriptions the committee, after discussion, had come to the conclusion that it be limited to one guinea.

Dr. A. WALLACE, in seconding this resolution, said that he considered that Dr. Glover had struck the note which had determined the committee to make a limitation of the subscription, for it was to the rank and file of the profession they must appeal for this noble cause. He was second to no one present in his admiration and appreciation of Semmelweis, for as a practitioner of obstetrics and a former teacher, he had long ago learned to realise the value of Semmelweis's discovery. As a junior student in the Royal Infirmary of Glasgow he was privileged to watch the early experiments of Lister in antiseptics, and the exercise of that same spirit, so beautifully put by Sir Andrew Clark, of the scientific instinct. The labours of these two men, though quite independent, were naturally associated in his mind.

The fourth resolution, proposed by Mrs. GARRETT ANDERSON and seconded by Dr. GRAYLY HEWITT, was to the following effect:—"That the carrying out of the above resolutions be relegated to a professional committee, with power to add to their number, with Sir Spencer Wells as chairman, Dr. Cullingworth honorary treasurer, and Dr. Boxall honorary secretary."

A vote of thanks to Sir Andrew Clark for his able conduct in the chair was felicitously proposed by Dr. Cullingworth, and the meeting separated.

## CHOLERA.

### CURRENT NOTES, COMMENTS AND CRITICISM.

THIS disease, although it has greatly abated, still continues to prevail in many places and to linger in others where it had manifested itself with more or less intensity during the autumn months. It is not so much the number of cases at any given place as the occurrence of a small number of attacks at so many different localities widely separated from one another that is so significant, for this serves to indicate how widely distributed the disease-cause is. In the case of a malady like cholera it unfortunately happens that the time of its distribution is not necessarily the season of its epidemic manifestation; the seed-time and harvest-time do not always follow one another closely. At Hamburg the official statistics of the disease for the last nine weeks since its first appearance in the city show that 17,989 persons were attacked, of whom 8261 died. The latest accounts report seven fresh cases and two deaths for the 26th inst. There still remain in the hospitals under treatment more than 400 cases. It is stated that the outbreak of epidemic cholera having subsided at Hamburg, the immigration of pauper aliens—mainly Russian and Polish Jews—into England has already recommenced. If this be so, it is to be regretted, we think, for with the winter before us any addition to our east end of London population can only tend to increase the poverty, overcrowding and disease already prevalent there. Fresh cases of cholera are reported from Amsterdam, Rotterdam, Huysen, Kondekerk, Utrecht and Semlin. Twenty-one deaths occurred in Holland during the past week. From St. Petersburg we learn that cholera has disappeared from Astrakhan. Since the outbreak of the epidemic there have been 125,000 cases of cholera and 65,000 deaths in the Caucasus, nearly 31,000 cases and over 11,000 deaths in the province of Saratoff, while at St. Petersburg the total number of cases has been 3300, with about 1150 deaths. At Warsaw 20 deaths have occurred from cholera, which broke out in that city from two to three weeks ago. At Budapest the disease continues, fresh attacks occurring daily, but the numbers seized and the fatal cases are diminishing. There were 23 cases and 11 deaths at Budapest from cholera on the 26th inst. The disease has reached Vienna, after having previously prevailed for some weeks in Galicia and Hungary. One fatal case occurred in Vienna on the 23rd, and another on the 24th inst., followed by a few other cases of cholera. There seems to be some difference of opinion as to the origin of these cases. By some they are attributed to the drinking of water from the river Danube, by others the disease is supposed to have been introduced by bales of rags from Budapest, but the assigned causes are purely conjectural, and rest on no scientific basis or real investigation of the facts. There have been other suspicious cases in Vienna, but the disease is not epidemic and has not given rise to any alarm. As regards France, there have been a few fatal cases at Marseilles during the week. The presence of cholera at Calais is officially announced; there have been 3 cases and 1 death in the town and 5 cases and 3 deaths in the neighbouring village of Barrate. It is alleged that at the present time there are several cases in the town, and the authorities are adopting very energetic measures. The disease is supposed to have been imported from the fishing village of Le Portel, near Boulogne. According to a report laid before the Hygienic Committee at Paris there were 90 deaths from choleraic disease in various parts of France from the 16th to the 22nd October. Of these, 9 were reported in Paris, 7 at Havre, and 33 at Marseilles. An important debate took place at the opening of the sitting in the Chamber on M. Raspail's presenting a Bill for the construction of a sewage canal from Paris to the sea, at which M. Proust, the Government Commissary, made a long speech in which he defended the present system. M. Proust rejected the idea of a canal carrying all the sewage water direct to the sea, and pointed out that the parallel currents in the English Channel would throw back all the filth on to the shore and contaminate the coast for a long distance. He alluded to the diminished violence of the different cholera epidemics from 1832 to that of 1892 and

considered the improvement was due to the improved sanitary arrangements. The best plan of disinfecting the river Seine was to increase the number of sewage farms in the direction of the sea. M. Raspail's Bill was rejected by the Chamber.

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### VISIT TO HAVRE.—PART II.

WASHERWOMEN AND THE DISINFECTING OF ALL LINEN.—THE DISTRESS.—POOR RELIEF AS A PROPHEXY.—MEASURE.—THE HAVRE SANATORIUM.—THE WATER-SUPPLY AND THE SHIPPING.

It has already been explained with what energy the authorities at Havre proceeded to isolate the sick and to disinfect their premises. So much energy was shown that in some cases patients were removed to the hospital and the premises they occupied were disinfected, though the occupants were not suffering from cholera. At my hotel, for instance, the servant, being overworked, was suffering from nervous exhaustion. Neighbours noticed that she had not been seen for two days, and rumours of cholera soon began to circulate. The young woman was therefore conveyed to the cholera wards of the hospital. There had been no vomiting and she was suffering from constipation. The attendants applied hot frictions, though she did not feel cold. Of course the mistake was soon discovered and the patient removed from the cholera wards. The incident proves that, if anything, the authorities sinned by excessive zeal. But for the first cases no such zeal was displayed, and it is now impossible to trace the cause of the spread of the disease. The woman who was taken ill on July 5th carefully concealed the fact that she came from the infected suburbs of Paris. Also it was not generally known that cholera prevailed in the neighbourhood of Paris, therefore no special precautions were taken. It was much later, and when the epidemic had already developed, that the first patient stated she had been to Courbevoie, but she could not remember where she had sent her soiled linen to be washed. The same uncertainty exists with regard to the second case, which occurred on July 13th and not far from the first case. It was only when a death occurred on July 15th—and this was the fourth case of cholera—that any precautions were adopted. This is the only explanation as yet forthcoming. To this early neglect is attributed the easy spread of the epidemic. If the epidemic spread easily it was also checked with comparative facility when once the sanitary service was thoroughly organised. I have already described at some length the measures taken, but there still remain in this respect some important facts to be recorded.

Havre was not the only town contaminated. Cases of cholera occurred in a number of surrounding towns and villages and it was noticed that washerwomen especially fell victims to the malady. Thereupon the mayors of the neighbourhoods where linen from Havre was brought to be washed adopted a very energetic measure. They decreed that no linen should be brought on the territory of their respective communes unless such linen had been previously disinfected by steam superheated under pressure. All the linen—not the infected linen, but all the linen now given to a washerwoman—is first taken to a disinfecting stove, and it is only when a ticket is attached to the linen notifying that it has been properly disinfected that the washerwoman is allowed to take it out of the town and wash it. Since this rule was enforced not a single case of cholera has occurred in the neighbourhoods near Havre where washerwomen live, though, as already stated, there were numerous cases before the linen was disinfected. The Minister of the Interior has taken similar precautions against Havre with a view to protecting the rest of France. A doctor is on duty at the railway station; he watches the passengers who are about to start; he has the power to prevent anyone leaving Havre who may appear to be ill. Of course persons who are ill do not generally travel, so that I do not believe anyone has been stopped. A great many passengers, however, have had to open their trunks, and if they had soiled linen it has been detained and disinfected. The doctor on duty has a list of all the addresses where cases of cholera have occurred, and asks the passengers where they come from. If they come from a house known

to have been infected the medical inspector proceeds to a more rigorous examination of their luggage. As a rule this service has been carried out with the greatest leniency, and many passengers are not even aware that they are the subjects of special observation. In other instances the linen is merely sprinkled over with the spray of sublimate used for disinfecting rooms. This latter process seems to be a most futile proceeding. The sort of pump used is very powerful; it sends forth a spray with great force, and doubtless, when brought to bear upon a surface, the disinfection of that surface is complete; but a bundle of soiled linen cannot be thus disinfected. Each article would require to be spread out, and this cannot be done in a railway station and during the few minutes there may be to spare before the departure of the train. On the whole this watch established over travellers who leave Havre is not likely to have rendered very great service, except in an indirect manner.

It is probable that the town of Havre has lost something like two millions sterling through the cholera epidemic. Dockers, labourers and others at Havre were thrown out of employment and thronged to the Hôtel de Ville. They crowded the corridors and the passages, clamoured at the gates, gathered in crowds on the open space before the municipal buildings. The position was critical. All the troops generally garrisoned at Havre were away at the grand annual manoeuvres. In the crowd there were a great number of women and children, who shrilly clamoured for food. Others were weeping, and not a few by their dignified yet distressed attitude clearly denoted that they were honest, hard-working people. It was impossible to refuse relief. There is a municipal bakery at Havre as at Paris. Tickets for bread at the municipal bakery were freely distributed. Then tickets for soup were also given. Apart from local resources the municipality received £6000 from the Government for the relief of the distress. When this became known every touter, every beggar, every impostor came pouring into the town from many miles round. When they obtained tickets for bread they handed them over instead of cash to the keepers of low dram shops. The latter obtained in exchange either money or bread from the bakers, who, in their turn, were reimbursed in cash by the municipality. Thus a good many tickets given for bread were in reality spent in drink. During the month of September the sum spent in giving tickets for soup, bread &c. amounted to about £80 per day. Now that the distress is not so widespread and that impostors have been discovered and dismissed the cost does not exceed £44 per day. Apart from this, a public subscription has yielded a sum of £8000, which for the most part is being spent to help the families of those who have died from cholera. All these difficulties with regard to the relief of the poor are important questions which have a very practical bearing in dealing with an epidemic. It is very certain that if a large section of the population had been left to starve the epidemic could not have been checked in so short a time.

In one respect the municipality of Havre has fallen short of what might have been expected. Great difficulties in dealing with the epidemic arise from the dirty habits of the people. The Normans are comparatively clean, but there is a colony of some 12,000 Bretons at Havre. They are for the most part navvies and labourers who came from the neighbouring province of Brittany when the docks were being constructed. They were followed by their families and have remained here ever since. They are notoriously the most obstinate and ignorant population of France. A great many of these people have been recipients of relief, and the assistance thus given might have served as an object lesson in cleanliness. It would not have cost much more to engage the services of one or two extra helpers to keep the place scrupulously clean, to establish a lavatory and to insist on personal cleanliness.

At the sanatorium matters were better managed. The Chambers of Commerce lent the town one of the handsome iron dock sheds. This fine structure measures 100 metres in length, 22 metres in width and is 17 metres high. Here were sent the inhabitants of houses that were being disinfected. On entering each person was placed in a bathing machine, which had been brought up from the beach for this purpose, and was made to undress and to wash. The clothes were taken away and disinfected, new clothes being lent and very often given in their stead. With a rough wooden framework and some canvas the floor of the shed was partitioned off and divided into rooms, small and large, so that families might be

separated one from the other and a certain amount of privacy might be maintained. At one end of the shed there was an oven, and here meals were cooked; at the other end a separate partition was called the infirmary, and here those who were taken ill could be kept apart till the hospital ambulance came to fetch them. This sanatorium was opened on Sept. 5th and closed a few days ago. In all 296 persons slept there, and the greatest number present at any one time was eighty-six. It has been calculated that the cost for food &c. amounted to 1s. 3d. per day per head. It was difficult to persuade the people to leave their homes and go to the sanatorium, but when once there it was still more difficult to get them to return to their homes. All the inmates having come from houses infected with cholera, it was natural to expect that some among them were in the period of incubation. This expectation was realised in six instances. It is very important to note that all these six cases occurred within two days of their arrival at the sanatorium. In no case did the period of incubation last beyond two days. This experience is of course of too limited a character to enable any conclusions to be drawn, but it should be compared with what has been noted elsewhere under similar circumstances. Already the French authorities are convinced that the period of incubation for cholera does not extend beyond five days.

In coping with the cholera epidemic the authorities at Havre have possessed the inestimable advantage of a good supply of pure spring water. Formerly there was a private company which had the monopoly of the water-supply, but it was felt that the private interests of the company might clash with public interests, and in the spring of 1884 the town bought all the rights of the company, which had been conceded for a period of ninety-nine years. It was agreed that the town should pay to the company for the seventy-one years that still remained to complete the term of the concession the subscription for water which the company was receiving. The value was calculated on the average of the previous six years and amounted to the sum of £15,000 per annum. This is a very heavy tax on the town, but the number of subscribers to the water-supply have now increased and the receipts for the year 1891 were equal to £17,840. More important far than this profit of close on £3000 in the year is the fact that water is much more widely distributed.

Leaving aside for the moment the question of the water that may be required for the purposes of drainage, the most important consideration is that at Havre no other water is available save that given by the town. In most of the places I have so far visited there were by the side of the town water-supply, which was generally pure, any number of private wells or rain-water cisterns where the water was anything but pure. The danger has arisen from the fact that in many circumstances it is not possible to ascertain whether the water used came from the public supply or from some private source. At Havre this danger does not exist. Nearly all the water is taken at the source of the St. Laurent and brought to Havre in a closed aqueduct. This water is hard but pure, and the yield is 21,000 cubic metres per day. From five other and nearer springs 2500 cubic metres more of water are secured and brought to Havre. At first it was thought that the cholera was due to the contamination of one of these minor springs, but on analysis it was shown that the water was only a little harder than that of the St. Laurent. Also, and this is more to the point, the district to the north-east of Havre supplied by these minor springs is almost entirely exempt from cholera. As for the water of the St. Laurent, it was drunk equally in the districts where there were the greatest number of cases of cholera and in the districts totally exempt from the disease. Under these circumstances the water-supply of Havre cannot be regarded as a factor in the spread of the epidemic; and by and by I shall have an opportunity of showing that this is the case not only in respect to the cholera, but also to other diseases, notably typhoid fever.

As Havre is the second seaport town of France, and, in normal times, a large number of ocean-going passenger-ships leave this port, it is a matter of international interest that these ships should have on board pure water. The water on board ships, as well as the passengers the ships carry, may be a means of spreading disease. But it is not necessary to point out how essential it is that only the purest water should be used during a sea journey. The fact now to be noticed is that at Havre, where so many sanitary defects exist, there is at least this one great advantage—a supply of water free from contamination, and there is no other and less pure source

at hand. Thus there is no danger that through ignorance, carelessness or for motives of economy impure water should be given instead of the spring water provided by the town.

Havre, Oct. 23rd.

#### CHOLERA IN AUSTRIA-HUNGARY.

The first case of cholera occurred in Vienna on Oct. 21st, when a coachman who was working on the Danube embankment was taken ill with symptoms of acute gastro-enteritis and was brought to the hospital for epidemic disease, where he died on the 26th. The bacteriological examination made by Professor Weichselbaum proved the presence of cholera bacilli and at the post-mortem examination the case was declared to be one of cholera Asiatica. In this case the patient had drunk large quantities of Danube water before his admission to the hospital, and it is believed that the infection may have been due to this influence. Fortunately the population of Vienna has not to rely on the drinking of Danube water, which would prove by this fact to be a source of cholera infection, and the navigation on the Danube will be stopped this week to prevent dangers arising from this side; but there are so many industrial and trading establishments situated on the embankments of the Danube that sporadic cases of cholera may be expected to occur there. Two other cases of suspected cholera were also brought to the hospital for epidemic diseases on Tuesday, but the bacteriological examinations have not yet been concluded. In one of the suburbs of Cracow Piaskiwickje, 12 cases of cholera have occurred during the last week, and sporadic cases were observed in some of the Polish villages near Cracow. At Budapest cholera showed the same morbidity and mortality as in the previous weeks, and 20 to 25 cases with 12 to 18 deaths are reported there daily; and at least 50 cases are occurring daily in the different towns and villages which have been infected already from the capital. Southwards it has reached Semlin, the town opposite to Belgrade; eastwards Temesvar, and northwards Pressburg. Two sporadic cases of cholera have occurred in Bohemia, both having been reported from Germana and Galicia. Three suspected cases have occurred at Pettau (Styria). It seems also that the germs of the disease are widely dispersed in the water of the rivers, and a Cracow physician was able to get cultures of comma bacilli out of the water of the Vistula river far away from Cracow. One of the most recent discoveries relating to the bacteriology of cholera, made some time ago by Professor Hueppe of Prague and his assistant, Dr. Scholl, has been disproved here by the experiments made by Professor Max Gruber of Vienna. Professor Hueppe had made cultures of the cholera microbes in hens' eggs, which were closed after their inoculation with the bacilli and exposed to the heat of the incubator; and he had maintained that by intra-peritoneal injection of the cultures thus obtained from the egg albumen all the characteristic symptoms of cholera could be obtained. Dr. Scholl then tried to separate the poisonous principle produced by the action of the bacilli in the egg albumen by treating it with water and alcohol. He obtained an aqueous extract which when injected into the peritoneum of animals produced severe symptoms of poisoning, especially paralysis of the muscles. But he had omitted to make control experiments with fresh, not infected, pure egg albumen treated in the same way. These control experiments have now been made here by Professor Gruber, and proved that by the method of Dr. Scholl a highly poisonous albuminoid body could be obtained even from perfectly fresh egg albumen.

**THE ROYAL BRITISH NURSES' ASSOCIATION.**—Sir William Savory presided at a meeting of the council of this Association on the 21st inst., at 20, Hanover-square. Princess Christian was also present. After the presentation of the report of the executive committee Dr. Bedford Fenwick briefly narrated the history of the labours of Miss Kate Marsden among the lepers of Siberia, and announced that the council had decided to bestow upon that lady the silver medal of the Society. The decoration was then pinned by Her Royal Highness upon the breast of the recipient of the honour, and the Princess read a statement expressive of her gratification that two of the members of the Society, Misses Annésley and Henrietta Kenealy, had distinguished themselves by the efforts they had put forth on behalf of the sufferers from cholera at Hamburg.

## THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5.30 P.M. on Oct. 20th, 1892, at 36, Grosvenor-street, Mr. George Pollock, President, in the chair. There was a very full attendance. Letters of regret at inability to be present were read from Mr. Mayo Robson, Mr. Purnell, Mr. Vincent Bell, Dr. W. J. Collins and Mr. A. T. Norton. The minutes of the previous meeting, which had been held over for confirmation, in order to allow of the entry of important letters referring to certain matters at issue between the Association and an official of the Royal College of Surgeons, were read and confirmed. At the previous meeting a subcommittee, consisting of the President, Mr. T. Holmes, Mr. John Tweedy and the honorary secretary, was appointed to draft a reply to statements made by the gentleman referred to in substantiation of allegations reflecting upon the accuracy of documents issued by the Association. The subcommittee met on Oct. 15th and now presented the draft reply. This reply was considered clause by clause, carefully revised and unanimously passed. The honorary secretary was directed to have it type-written in the amended form and forwarded without delay to the official of the College. The Committee sat till 7 P.M., when it adjourned, there being no time for further business.

## THE LATE SUPERINTENDENT OF THE ROYAL INFIRMARY, EDINBURGH: DEPUTY-SURGEON-GENERAL FASSON.

THE Army Medical Department may well feel proud of the late Deputy-Surgeon-General Fasson, who received his training in the Army Medical Service.

At the meeting of the Board of Managers of the Edinburgh Royal Infirmary, held on Monday, the following minute commemorating the services of the late Deputy-Surgeon-General Fasson was approved of:—

"The managers record their sense of the great loss sustained by the Royal Infirmary in the death of Mr. Fasson. Appointed superintendent of the infirmary in 1871, he brought to the work of his office a combination of gifts and experience which singularly fitted him for its important duties, and these he has throughout discharged with eminent ability, unwearied assiduity, and well-deserved success. That work included the difficult and responsible task of transferring the infirmary to the present buildings, and the reconstruction, to a large extent, of its administrative department. Yet by no startling change, but by the steady introduction of improved methods of which he had satisfied himself was reform carried out. Ever intent on schemes for securing smoother and more efficient working of the hospital, he gladly welcomed and adopted suggestions from any quarter which tended in this direction. Firm in his administration, exact in his demands upon himself, and expecting equal fidelity and efficiency in others, his relations to all whose duties he had to superintend were distinguished by great consideration and courtesy. It was in no small measure due to the practical sagacity and foresight of Mr. Fasson that the fever wards of the infirmary were in 1886 transferred to the city authorities—a change which, as the event has proved, has been greatly to the public advantage. The nursing department of the infirmary underwent entire reconstruction during Mr. Fasson's tenure of office. This was a work in which he took a profound interest, and the high position which the Royal Infirmary now holds among hospitals as a training school for nurses owes much to his ever-ready and hearty sympathy and coöperation. In providing the nurses with adequate accommodation Mr. Fasson warmly interested himself, and the building of the new home, now nearly completed, was undertaken by the managers largely upon his strong recommendation. The arrangements for its furnishing and occupation were engaging his attention in the last days of his life. The tone which happily pervades every department of the noble institution with which Mr. Fasson was so long and honourably connected is undoubtedly to be ascribed to the influence which he quietly but most effectively exercised. Of Mr. Fasson's personal qualities it is impossible to speak too highly. His gentleness, his perfect fairness, his unvarying courtesy and his tenderness of heart endeared him to all by whom he was known. These qualities ever worked outward from what were the dominating influences of his life—high principle and Christian character. The managers share deeply in the feeling of personal loss which Mr. Fasson's death has evoked in all who in any capacity minister within the walls of the infirmary, and they are keenly sensible of the very difficult duty which, through his death, has devolved upon them of finding a superintendent worthy to succeed him. They resolve that an extract of this minute shall be sent to his afflicted family, with the assurance of the managers' heartfelt sympathy with them in their bereavement."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6280 births and 3524 deaths were registered during the week ending Oct. 22nd. The annual rate of mortality in these towns, which had been 17.8 and 17.3 per 1000 in the preceding two weeks, rose again last week to 18.0. In London the rate was 17.7 per 1000, while it averaged 18.3 in the thirty-two provincial towns. The lowest rates in these towns were 7.9 in Croydon, 12.4 in Birkenhead, 14.1 in Derby, and 14.9 in Halifax; the highest rates were 21.3 in Burnley, 21.7 in Leeds, 22.9 in Oldham, and 23.0 in Preston. The 3524 deaths included 387 which were referred to the principal zymotic diseases, against numbers declining from 991 to 389 in the preceding seven weeks; of these, 94 resulted from diarrhoea, 88 from measles, 68 from diphtheria, 58 from scarlet fever, 46 from "fever" (principally enteric), 29 from whooping-cough, and 4 from small-pox. These diseases caused the lowest death-rates in Birkenhead, Wolverhampton, Bristol, and Blackburn; and the highest rates in Salford, Plymouth, Oldham, Sunderland, and Preston. The greatest mortality from measles occurred in Croydon, Plymouth, Oldham, Leicester, and Salford; from scarlet fever in Plymouth and Swansea; from "fever" in Preston and Sunderland; and from diarrhoea in Bradford, Norwich, Sunderland, and Preston. The mortality from whooping-cough showed no marked excess in any of the large towns. The 68 deaths from diphtheria included 41 in London, 5 in Birmingham, 4 in West Ham, and 4 in Manchester. Two fatal cases of small-pox were registered in Oldham and 2 in Halifax, but not one in any other of the thirty-three large towns; 3 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 2 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3936, against 3515, 3628 and 3797 on the preceding three Saturdays; 484 new cases were admitted during the week, against 412 and 503 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 241 in the preceding seven weeks, further rose to 267 last week, but were 72 below the corrected average. The causes of 82, or 2.3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bolton, Leeds, Sunderland, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, and Hull.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18.5 and 18.0 per 1000 in the preceding two weeks, rose again to 19.0 during the week ending Oct. 22nd, and was 1.0 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 8.6 in Perth and 14.1 in Dundee to 20.4 in Aberdeen and 25.1 in Edinburgh. The 529 deaths in these towns included 39 which were referred to measles, 15 to scarlet fever, 14 to diarrhoea, 10 to whooping-cough, 5 to diphtheria, 4 to "fever," and not one to small-pox. In all, 87 deaths resulted from these principal zymotic diseases, against 78 and 75 in the preceding two weeks. These 87 deaths were equal to an annual rate of 3.1 per 1000, which exceeded by 1.1 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 12 to 33 in the preceding four weeks, further rose to 39 last week, of which 26 occurred in Edinburgh, and 10 in Aberdeen. The deaths referred to scarlet fever, which had been 16 in each of the previous two weeks, were 15 last week, and included 8 in Glasgow, 3 in Edinburgh, and 2 in Paisley. The 10 fatal cases of whooping-cough exceeded by 2 the number in the previous week, and included 5 in Glasgow, 3 in Edinburgh, and 2 in Paisley. The deaths from diphtheria, which had declined from 10 to 2 in the preceding three weeks, rose again to 5 last week, of which 2 occurred in Aberdeen. The 4 fatal cases of "fever" differed but slightly from those

recorded in recent weeks and included 3 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 84 and 82 in the preceding two weeks, rose again to 97 last week, and were within one of the number in the corresponding week of last year. The causes of 49, or more than 9 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20.0 and 20.7 per 1000 in the preceding two weeks, declined again to 19.4 during the week ending Oct. 22nd. During the first three weeks of the current quarter the death-rate in the city averaged 20.0 per 1000, against 17.1 in London and 20.9 in Edinburgh. The 130 deaths in Dublin during the week under notice showed a decline of 9 from the number in the preceding week, and included 4 which were referred to diarrhoea, 2 to "fever," one to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. In all, 7 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.0 per 1000, the zymotic death-rate during the same period being 1.8 in London and 7.9 in Edinburgh. The fatal cases of diarrhoea, which had declined from 20 to 3 in the preceding three weeks, were 4 last week. The deaths referred to different forms of "fever," which had been 2, 3, and 4 in the preceding three weeks, declined again to 2 last week. The 130 deaths registered in Dublin last week included 31 of infants under one year of age and 32 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons slightly exceeded those recorded in the preceding week. Two deaths from violence, but no inquest cases, were registered; and 29, or nearly one-fourth, of the deaths occurred in public institutions. The causes of 17, or more than 13 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

#### THE EFFECT OF THE LEBEL RIFLE.

To military surgeons and others who have been experimentally studying the effect of different arms of precision and of bullets of small calibre with high initial velocity on the carcasses of dead animals the experience gained by the French in the war in Dahomey will be of much interest. Everything appears to depend upon the distance at which these small-bore bullets are fired. At a great distance they inflict very clean wounds, which might not be fatal unless some vital part were struck and their "stopping power" might, it is supposed, be relatively small. But at short distances their effect is very different, and the wounds are said to resemble those made by explosive bullets. According to the somewhat sensational description of the first encounter of the French expeditionary corps in Dahomey with Behanzin's forces, published in the *Figaro*, the effects of the Lebel rifle were a revelation for everyone. The largest trees afforded no shelter for the enemy, for they were pierced right through; and it is difficult for those who have not actually seen it to form any idea of the nature of the wounds and the rending action of the projectile on the human body. As the correspondent of the *Figaro* mentions that the attacking force numbered about 4000 men and that the attack itself was of the nature of a surprise the distance which separated the Dahomey native force from the French was inconsiderable—barely more than thirty yards from the tents of the headquarters' staff—at the first onrush—when the fighting was most severe and the destruction caused by the Lebel rifle greatest. The official account of the battle and further particulars as to the effect of the Lebel weapon will probably furnish us with more correct information than we possess at present.

#### MOVEMENTS OF MEDICAL STAFF.

SURGEON-MAJOR JAMES has been transferred from Shornecliffe to Windsor. Surgeon-Major Ring has resumed duty at Belfast. Surgeon-Lieutenant-Colonel Duke has assumed charge of the Station Hospital at Canterbury. Surgeon-Captain Wiles has joined at Worcester. Surgeon-Captain Long has resumed his duties at Sierra Leone after sick leave. Surgeon-Captain Kay has succeeded Surgeon-Captain Cotrell in Medical Charge of the Women and Children's Hospital at

Chatham. Surgeon-Captain Stanistreet has joined at Dover for duty. Surgeon-Lieutenant-Colonel Hensman and Surgeon-Captain Hamilton have arrived with the 1st Life Guards at Shornecliffe.

#### REGULATIONS IN INDIAN SERVICE.

We understand that the medical officers proceeding to India to carry out the reliefs this trooping season are not detailed to specific presidencies as heretofore, but are for service in India generally, their destination being left in the hands of the authorities in India. This change, dictated presumably by local requirements, appears at the first blush an unmixed evil as far as the officers themselves are concerned, for choice of presidencies, when permitted, was doubtless a great privilege; but, on the other hand, when there was no choice—which must frequently have happened—the whole tour of service had to be performed in the presidency apportioned, whereas it may be assumed that under the new system changes from presidency to presidency will be constant.

#### ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Oscar Frederick Molloy retires on retired pay. Surgeon-Major John Edward Vaughan Foss, from half-pay, to be Surgeon-Major. Surgeon-Major-General G. L. Hinde, C.B., having attained the age of sixty, will be placed on retired pay.

#### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain David Edgar Flinn, F.R.C.S. Irel., to be Surgeon-Major.

#### INDIAN MEDICAL SERVICE.

Surgeon-Captain F. P. Maynard, 13th Bengal Infantry, has been granted leave to proceed out of India on private affairs. Subject to Her Majesty's approval the following Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels:—A. S. Lefthbridge, M.D.C.S.I., A. Stephen, M.D., and J. H. Newman, M.D. Surgeon-Lieutenant-Colonel F. Lyons, M.D., is transferred to Poona district and appointed to the Medical Charge of Station Hospital, Poona. Surgeon-Lieutenant-Colonel J. Riddick, on arrival from England, is appointed to the Medical Charge of Station Hospital, Colaba, vice Surgeon-Lieutenant-Colonel F. Lyons, M.D., transferred to Poona. Surgeon-Major W. A. Simmonds has assumed Charge of the Civil Medical duties of the Hazara district. Surgeon-Captain F. R. Ozzard has assumed Charge of the Civil Medical duties of the Kohat district. Surgeon-Lieutenant-Colonel Edward Mulvany and Surgeon-Major George Augustus Cones have retired. The Queen has approved of the following admissions to Her Majesty's Indian Medical Service, to be Surgeon-Lieutenants:—Bengal: Patrick Balfour Haig, Thos. William Archer Fullerton, Ralph Henry Maddox, Edward Victor Hugo, Harry George Melville, Arthur Oldham Hubbard, Charles George Robson Scott, Herbert Austen Smith, Douglas Richard Green, Geo. McIver Campbell Smith, Hubert Malins Earle and Joseph Geo. Hulbert. Madras: Pulteney Charles Gabbett and John Lewis Macrae. Bombay: Francis Edwd. Swinton, Sidney Harvey Burnett and Thomas Jackson.

#### VOLUNTEER CORPS.

1st Lincolnshire (Eastern Division, Royal Artillery): Surgeon-Lieutenant E. B. Reckitt is promoted to Surgeon-Captain.

#### THE LATE SURGEON-GENERAL MILLS CANNON.

We regret to have to announce the death of Surgeon-General Henry Mills Cannon, in his seventy-third year. He died at his residence, 10, Eaton-place, S.W., on the 12th inst. The deceased, who entered the Army in 1846, served in the Punjab Campaign of 1849-50, and was present at the actions of Ramnuggur, Chillianwalla, and Goojerat, receiving for his distinguished services a medal and three clasps. He earned the thanks of the Supreme Government and of the Local Government of the North-Western Provinces for services in the Rohilkund and Meerut Divisions during the Mutiny period. He was also recommended by the Commander-in-Chief for brevet promotion, and a good-service pension of £100 a year was conferred on him.

#### DEATH OF SURGEON-GENERAL H. R. OSWALD, M.D.

We regret to record the death at Edinburgh of Surgeon-General H. R. Oswald, M.D., after a lingering and painful illness, on Oct. 15th last. Dr. Oswald entered the Indian Medical Service as assistant surgeon in 1850, and was employed in the Madras Presidency. Having undergone the usual experiences in different stations of a junior surgeon, he was appointed for a brief period to attend Dr. Deatly

Lord Bishop of Madras, on his tour of visitation. Subsequently, in 1853, he was transferred from B Troop, Horse Artillery, to proceed on active service in Burmah under the officer commanding the Madras Division of the Army of Ava. He served in the second Burmese war till invalidated from the Pegu Division back to Madras, and in 1854 obtained special civil employment in the Mysore Commission, of which he obtained full medical charge in 1865 at Bangalore. His promotion to the rank of Surgeon-Major followed in 1870, but he continued his civil duties till 1876, when he was raised to the administrative rank of Deputy Surgeon-General and once more found himself in Burmah. In 1879, however, Dr. Oswald was made Surgeon-General of the Madras Presidency with temporary rank. His retirement with the rank of Surgeon-General took place in 1881, previously to which he had been in charge at Secunderabad of the Hyderabad Subsidiary Force and Hyderabad Contingent. Such is a brief record of an active life always marked by an able and conscientious discharge of duty. In his various capacities—civil, military or social—Dr. Oswald obtained the esteem and respect of his seniors and the love of his subordinates. Graceful in bearing, of a fine appearance, courteous in manners, and unvarying in kindness, few officers in his service have obtained a wider or better deserved popularity than his—a popularity which attended him also in private life. His loss will be mourned by a wide circle of friends both in and beyond his profession as well as by his family.

#### ARMY COMPETITIVE EXAMINATIONS AND PHYSIQUE.

We are glad to notice that our "Service" contemporary, the *Broad Arrow and Naval and Military Gazette*, has called attention to the question of the value which should be attached to physical qualifications at entrance examinations for the military services. Whilst recognising the difficulty of devising a practical scheme for carrying this out, we nevertheless consider that superior physical qualities should certainly count for something in a candidate for a commission in the army; whereas at present a candidate who is, as far as physical qualifications go, a well-grown, fine young fellow, proficient in manly games and exercises, enjoys no advantage over other candidates whose physical qualifications perhaps only reach the required minimum standard. No doubt mental and physical energy are frequently combined in men of small stature, and it would be easy to cite instances of such who have distinguished themselves in all walks of life, including the army and navy. Still, the possession of physical attributes, manliness and vigorous health are most important qualifications for a soldier, and our system of competitive examination takes no account of these, except to exclude those who are unfit in this respect, and the youth who is perhaps a bookworm with good receptive faculties enjoys a manifest advantage over other and more desirable candidates in every other respect. It does not at all follow either that the youth who successfully passes a competitive examination will develop any intellectual superiority later on. Anyway, mental and physical powers are Nature's gifts, and as regards army candidates both are valuable; but only one is at present taken into account. There should not be any insuperable difficulty, we imagine, in devising a scheme by which very desirable candidates, as far as physical qualifications are concerned, with school certificates of proficiency in out-door exercises and games, should have a limited number of marks assigned them as the result of their physical examination. Some regulation might be framed by which youths of a given height, chest measurement and weight at different ages would be entitled to a certain number of marks, provided they were in all other respects physically fit and produced certificates of the kind we have indicated.

#### THE RUPEE.

Medical officers and others serving in India will be glad to learn that the Viceroy of that country has received a dispatch from the Secretary of State for India announcing that an India Currency Committee has been appointed under the presidency of Lord Herschell. The members of the committee are Mr. Leonard Courtenay, M.P.; Sir Thomas Farrer; Sir Reginald Welby, Permanent Secretary of the Treasury; Lieutenant-General Strachey; Mr. Currie, Member of the Council of India; and Mr. Arthur Godley, Permanent Secretary of the India Office. Lord Herschell was president of the Gold and Silver Commission of 1887 and 1888. The problem to be solved is no doubt an extremely difficult one, but we trust that some solution will be arrived at, as the present rate

of exchange and the depressed value of the rupee grievously affect the pockets of Europeans serving in India.

#### THE GERMAN ARMY BILL.

There appears to be a good deal of trouble hatching in Germany over the new Army Bill, the object of which is to decrease the length but to increase the strength of the military service by an enormous addition to the army of that country. Action and reaction follow one another in politics as in physics. The first Napoleon, by exacting that Prussia should only have a limited standing army, gave rise to the development of the German system of organisation which played such an important part in the Franco-German war of 1870, and the loss to France of Alsace and Lorraine has since led to the huge and increasing armies that have been since maintained in both those countries and in the rest of Europe. The addition that will require to be made to the medical service of the German army in the event of the new Bill passing, which does not seem probable, must be very considerable, and the amount of medical aid of all sorts that will be necessary in any actual campaign in future, with all the advances which have been made of late in the art of war, will severely tax the powers of any nation.

#### CHOLERA IN INDIA.

As regards the occurrence of the outbreak of cholera at Murree that was attended with a disastrous death record, to which attention was called in THE LANCET of the 15th inst., it appears, according to the Indian papers, that it is to form the subject of investigation. The cause of the outbreak was alleged by some to be attributable to importation, the disease having been conveyed by two regiments of Kashmiri infantry and a battery of artillery, who were subsequently attacked with cholera, having been allowed to pass from a district where that disease was prevailing through military camps and the station of Murree. On the other hand, it was rumoured—but with what degree of truth we do not know—that the use of contaminated water in the manufacture of soda-water was the cause of the attacks. The *Times of India* calls attention to a report by the Sanitary Commissioner of the North-West Provinces and Oudh, detailing the success which attended the sanitary arrangements that were made for the great Hurdwar fair last year. About three-quarters of a million of Hindoo pilgrims assembled to bathe in the sacred pool of the Ganges; but in consequence of the precautions that were adopted and the extreme care that was taken no epidemic or outbreak of cholera occurred, nor was the disease transported to other localities. This was contrary to the experience of previous gatherings of the kind. The Sanitary Commissioner considers that the experience obtained in 1891 proves that the disease is preventable by the adoption of due precautions and the immediate application of measures for arresting the spread of infection. The Government of the North-West Provinces, however, while giving every credit to the Sanitary Commissioner for the success of his sanitary measures on that occasion and recognising their immense importance in such cases, nevertheless hold that they are not necessarily effective in preventing the spread of the disease, and, by way of illustration, refer to their experience in connexion with another great native gathering where the same measures were followed without a similar amount of success. The Government of the North-West Provinces apparently would rather put their trust in dispersing fairs and turning back pilgrims on their way thither, and have applied to the Government of India for legislation to give them the power to do this whenever considered necessary. These pilgrimages are great religious ceremonies, and, it is presumed, could not be stopped without causing great fanatical discontent, otherwise their suppression altogether would probably be the best course to be adopted.

#### ALLEGED DEATH OF AN OFFICER FROM EATING TINNED FISH.

It is alleged as the result of a post-mortem examination on the body of Lieut. W. Huddleston, R.E., who was recently found dead in his bed at Chatham that death was the result of blood-poisoning caused by eating tinned fish. The deceased officer is stated to have complained of feeling ill shortly after having partaken of the tinned fish in question. The death of this young officer has given rise to much regret and sympathy in the garrison.

#### HOSPITALS IN INDIA.

The *Globe* of the 22nd inst., in an article on this subject, remarks that the institution of hospitals in India must be

regarded as one of the beneficial results of British supremacy and gives many instances of their good effects on the people and princes of India. It is not forgotten, our contemporary says, that some of the earlier and most important concessions to the Honourable East India Company were obtained by Surgeon Gabriel Broughton in 1645 for professional services rendered to the Mogul Emperor Shah Jehan. Some of the larger hospitals date from the period of the Governorship of Warren Hastings, when the whole service of civil hospitals was reorganised. Now this system of civil medical institutions, hospitals and dispensaries has attained enormous proportions, there being in 1890 1641 such, treating 265,000 in-door patients and 11,978,000 out-door, or a total of 12,243,000. It is worthy of note, while we in London are somewhat recklessly multiplying the facilities for medically helping those who can help themselves, it has recently been proposed in India to withdraw all Government aid from medical institutions in large and wealthy localities, which, having been taught the value of hospitals and dispensaries, ought to take on themselves the whole burden of their support.

"Audi alteram partem."

### "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—A licence to practise medicine for gain carries with it the privilege of so doing; the privilege belongs to the licence and without the licence the privilege does not exist. Medical aid associations are unqualified bodies carrying on practice and as a rule make considerable profits thereby. Whatever their aim or original intention might have been, I have shown elsewhere they, as a rule, make these profits. From these considerations the question arises: Is it not the confusion of the privileges of a qualified person and of an unqualified body of persons which originates the special pleading on behalf of these medical aid associations? A qualified man may legally carry on practice with a view to profit-making; he may invest his capital in such an undertaking, or by his skill create both capital and revenue; and he may properly employ such assistance at the current market price as necessity may demand. But is it right or proper for a body of unqualified persons to do these things? And if so, wherein is the value of a qualification? This is done, however, at the present time by medical aid associations under cover of a qualified man or in partnership with him, and the definition of the technical word "covering" must be very restricted indeed, in order to be rendered inapplicable to the condition of affairs.

The line of defence of the system of medical aid associations adopted by interested persons opens a very fine field for the profitable employment of capital, and before long we may have this field exploited, for things are already shaping in that direction. Upon the principles urged by your correspondent a company may run one or more medical practices for gain by employing qualified practitioners at a fixed salary. All the net profits will belong to the company, and as the directors do not personally practise it is alleged that the doctor does not cover them, nor is any professional offence committed. Based upon these principles it will be seen that a very taking prospectus could be drawn, and such a document might point out the following considerations amongst others: "The objects and conduct of the company will be similar to those at present adopted by medical aid associations—viz., to provide the thrifty poor, and especially the public generally, with excellent medical advice and medicine at a purely nominal price; and the scheme gives promise of large and increasing profits. It has been decided that there is no technical or legal objection to the course the company proposes to adopt, and as the proprietors and directors will not personally practise, no legal or professional offence is committed, and there is no possibility of any question of covering or other offence being raised in connexion with the business of the company. It has in fact been justly urged that such a contention is childish. It is intended to begin operations by the organisation of one hundred practices only, and for this purpose the services of a hundred duly qualified men will at once be secured. It has

been ascertained that the cost of these will be about £150 per annum each, rising, as the trade of the company develops, to £250. The other expenses, house rent, advertising &c., will amount to a similar sum; while directors' and managers' fees will not exceed £5000 a year. For a sum of £35,000, therefore, the first hundred practices will be fully equipped and maintained during the first year. It is expected that on the first year's trading a loss will result; that during the second year income and expenditure will balance; and that after this large and increasing profits will result. As the directors will be entirely beyond the disciplinary control of any authority, the company will have the advantage of unrestricted advertising and canvassing, and a contract has already been entered into, dated Oct. 22nd, 1892, by which admirably displayed advertisements will be posted by Messrs. Billhead and Co. As the salaries of the medical officers will be a fixed sum the proprietors will be in the happy situation of possessing the surplus profits, which under the old system belonged to the private practitioners. This fixed-wage system, too, will enable the company to supply excellent advice and medicine at prices very far below those ever offered to the public, and it is believed that very large profits will be made on farthing consultations. No injury will be done to the medical officer, for he will be in the desirable position of being in receipt of a fixed income, which is more than he could get in private practice, otherwise he would not accept it. It is true that the result of our system will probably be to transfer to the pockets of the shareholders profits generally acquired by the general practitioner and to degrade the profession of medicine; but, as we do not injure in any way our medical officers, these gentlemen tell us all other considerations may be ignored. Our medical officers will be bound down not to practise within the radius of the company's operations; and as this radius will, it is confidently believed, in a few years extend to every town in the kingdom there will be no fear of the company's permanent interests being injured by our medical men wishing to leave us or being dissatisfied when they are refused increased salaries. It has been ascertained from the experience of similar undertakings that one medical officer will be sufficient to deal with 3000 or 4000 patients. It is proposed to develop a very large midwifery practice by means of invitingly low fees, and if our medical officers should under the strain of night and day work permanently break down in health they will be, under existing circumstances, quite easily replaced without interruption to the company's business. It has been decided by worthy opinion that the term 'sweating' as applied to our desirable scheme is an unjust and improper one, and this view is shared by our prospective medical officers. The boon we offer to the public is so great that the scheme commends itself to all those who have the public interests at heart, and the suggestion that our work will act injuriously to the profession, and through it react upon the public, may be dismissed at once as prompted by selfish trade interests."

I will only add one word to this paraphrase of your correspondent's arguments. The profession should with one united voice protest, as I, an individual unit in that profession, vehemently protest, against the astounding indecency of your anonymous correspondent's threat. The General Medical Council has been entrusted by the State with the preservation of our professional principles, and as in the past so will it in the future fearlessly discharge its sacred trust with the unanimous support of our great profession, unseemly threats of democratic opposition notwithstanding.

I am, Sirs, your obedient servant,

LESLIE PHILLIPS,  
Secretary, Medical Defence Union (Limited).

Birmingham, Oct. 22nd, 1892.

To the Editors of THE LANCET.

SIRS,—Will you permit me to reply to a letter signed "Verax" in THE LANCET of last week, who endeavours to meet your charge "that the position we occupy in holding medical aid appointments is indefensible"? Before doing so, however, allow me to mention that Dr. Phillips has forwarded a copy of his letter to the General Medical Council and to the various resident medical officers. If "Verax" will only read this letter carefully through he will find that, if the recommendations contained therein are adopted, they will tend to improve materially the present position of the various resident medical officers ("Verax's" included), while having a tendency to prevent the further growth and development of these coöperative businesses. I cannot see, then, very much

for "Verax" to grumble about. In trying to place as roseate a complexion as possible on his present tenure of office your correspondent only tells half the story. I have had experience of several of these associations, having acted as locum tenens and assistant before accepting my present appointment as resident medical officer, which latter, I may say, I undertook "from sheer stress of circumstances." I am, therefore, in a position to supply some particulars which "Verax" has carefully ignored or left in the background. I may say I possess the acquaintance of many occupying a similar position to myself, and I have never yet met one who holds, or ever held, such an appointment that has not complained bitterly of the treatment received. The rules, management &c. of all these associations are based on similar lines. All the members of the association are generally supplied with a copy of the rules. There is one which is being continually brought under the members' observation—viz., "Complaints against the medical officer &c." From the copy which I enclose you can see it is somewhat similar to those generally placarded in omnibuses, so that to all intents and purposes, in the estimation of the management committee, a surgeon in this respect is placed on no higher a level than an omnibus conductor. It is no uncommon thing for me to be told—"You are our servant." "We keep you." "I will report you," &c. Does "Verax" consider that any medical man occupying a position of this character is upholding the dignity of the profession? It sometimes happens that members for very trivial causes lodge complaints with the managing committee, who, by the way, are empowered if they think proper to suspend you without a moment's notice. You are then duly summoned to appear before this august tribunal to meet the complainant. The latter is permitted to cross-examine the medical officer after making his statement, and in so doing the latter has to submit to the humiliating ordeal of being asked either by the complainant himself or his friends or the managing committee perhaps many insulting questions. Nothing, I assure you, Sirs, in my experience affords greater pleasure to some of these ignorant men than "sitting" on their intellectual superior. In one case I was reprimanded for being insolent to a member, the insolence consisting of a mild suggestion "that the said member might wash himself before coming to the surgery to see me directly from an offensive smelling occupation he was following." I trust "Verax" is more fortunate and experiences none of these unpleasant incidents.

I contend that it is quite unprofessional, as well as illegal, for any medical man to barter away portion of his midwifery or vaccination fees to the association. If the managing or general committees pay themselves for attending quite (to my mind) unnecessary meetings out of fees so earned, I see very little practical difference between this and covering. The more fees the committees obtain the more frequently they go "up and down the town" extolling the excellent qualities of the association and their doctor—all for the purpose of "bringing more grist to the mill." From the vast numbers I have to see between visiting and at the surgery—sometimes as many as one hundred and fifty daily—I find that I am inevitably drifting into very careless habits in examination and diagnosis. I am painfully cognisant of the fact that one day, only a very short time ago, having a great number of people to visit, I overlooked a case of intussusception not having time to make a sufficiently careful examination. Here is a life that might have been saved had I been otherwise circumstanced. This is not I regret to say a solitary incident. There are many other points in connexion with our appointments which from the length this letter has already reached I am unable to touch upon.

I trust, in conclusion, "Verax" will have the good sense to abandon his present untenable position, and throw in his lot with his brethren in endeavouring to ameliorate their position and terminate a system which, as far as my experience enables me to judge, I have no hesitation in characterising as an injury to the profession, a fraud on the public, besides being disgraceful in a professional sense to every medical man who countenances it by lending his support.

I remain, Sirs, yours faithfully,  
A MEDICAL AID OFFICER.

Oct. 20th, 1892.

To the Editors of THE LANCET.

SIRS,—Certainly something should be done to rectify these growing evils, and I appeal to the General Medical Council for their support. In your article on Dr. Leslie Phillips's

report you suggest that the remedy should come from individual members; but I maintain that it is useless looking for hope from that quarter, for though I hold one of these appointments I know perfectly well that if I resigned forty candidates are ready to take my place. A vigorous and determined stand should now be made, and, if aided by the Council, there should be no difficulty. Unless they are altered there will soon be no private practitioners, but plenty of "businesses" with patients as "customers."

I am, Sirs, yours faithfully,

Oct. 19th, 1892.

L. R. C. P. LOND.

## INTERNATIONAL MONUMENT TO SEMMELWEIS.

To the Editors of THE LANCET.

SIRS,—When I was preparing the Goulstonian Lectures on Puerperal Fever (1872), I was of course obliged to study deeply and widely its history. There was no point which interested me more than the claims put forward in favour of Semmelweis, and I think that I showed clearly to what extent such claims were justified. I found that these claims were advanced by those who were evidently not acquainted with the history of this subject and what had been done in this country long before the time of Semmelweis. I am not one of those who would discourage the expression of admiration for those who have worked unselfishly in the interests of science and humanity, but we must not sacrifice justice to generosity, otherwise more harm than good is done.

I am, Sirs, yours truly,

Savile-row, W., Oct. 24th, 1892.

ROBERT LEE.

## "COMPULSORY VACCINATION."

To the Editors of THE LANCET.

SIRS,—In reference to your paragraph about me I may say that I am not aware that I have made up my mind on the subject which I am investigating more than other members of the Commission. I held my present opinions long before I joined it and was appointed in succession to the late Mr. Bradlaugh because I was understood to hold similar views. I appeared before the Rochdale guardians as any other parent may do—my being a member of the Vaccination Commission was only a coincidence. I asserted that there are no known means of securing the purity of lymph or of limiting with certainty its inflammatory effects, and that serious results have occurred from vaccination. I also asserted that where isolation has been adopted it has been found effectual without vaccination, and when vaccination has been tried without isolation it has been found very ineffectual. Will any doctor deny these assertions? Small-pox is so rare that I think that the risk my unvaccinated children run of catching it is less than the risk of the injury which might come to them from vaccination, even supposing the protective powers of the operation to be as great as some think it is. I do not enter into the question as to how much the diminution of the disease is owing to vaccination and how much to better medical knowledge and improved sanitation—I speak of the present risk. I should not object to a Compulsory Isolation Bill.

I am, Sirs, yours truly,

Reform Club, Oct. 21st, 1892.

JOHN A. BRIGHT.

\* \* \* If it were possible to have a perfect system of isolation in every part of the land there might be no need for other preventive measures; but certainly we cannot agree that up to the present time, where "isolation has been adopted, it has been found effectual without vaccination." As regards the comparative risks referred to by Mr. Bright, we would venture to suggest that it is not a mere question of "catching" small-pox, but of having it in a severe and dangerous form.—  
ED. L.

## DEATH UNDER CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—I have to report a case of death under chloroform which occurred at Stockport Infirmary on Friday, Oct. 21st. The patient was admitted into the infirmary suffering from carcinoma of the rectum. He was an old man (aged sixty-three) and much emaciated, and though the heart was rather weak, still there was no valvular disease. Both the patient and his

friends were very anxious that an operation should be performed. Lumbar colotomy was proposed. The chloroform used in this case was Duncan and Flockhart's. Patient had been inhaling the chloroform for ten minutes, when his breathing suddenly became very shallow and pulse hardly perceptible. The administration of the anæsthetic was at once stopped and artificial respiration commenced, ether injected hypodermically, the head was lowered, legs lifted up and nitrite of amyl in capsules held before the nose. All, however, proved of no avail, though artificial respiration was kept up for half an hour. We have had very few deaths under anæsthetics in this infirmary. In a case previous to the above mentioned, which happened two years ago, the anæsthetic employed was ether and the operation was also for carcinoma of rectum. In neither case had the operation been commenced.—I am, Sirs, yours faithfully,

H. R. BELLAMY, L.R.C.S. & L.R.C.P. Edin.  
Senior House Surgeon to the Infirmary.

Stockport, Oct. 25th, 1892.

N.B.—The amount of chloroform used was only one drachm and a half.

## EXPERIMENTS ON ANIMALS.

To the Editors of THE LANCET.

SIRS,—General practitioners will agree with Dr. Tyson in his appeal for facts in support of vivisection. What we need is something definite to put before our patients to justify the position taken by the medical profession on the subject. The public is in search of the truth, and when we know that amongst the public are such men as Lord Coleridge and the late Serjeant Ballantine trained in the analysis of evidence, it is the worst possible policy on our part to treat them as a pack of hysterical women. We must remember they have the whole literature of the subject before them, and that it is useless to say the painful experiments are few and the pain trifling. When the public see the rivalry between distinguished professors and the undisguised pleasure it gives one to show how that all the experiments conducted by a brother experimenter are futile, they look upon the talk about a deep love for humanity on the part of the scientist as cant. The scientist is human, like the rest of us; research is his work, and the discovery of a new law is more to him than the possible applicability of the law and the needs of the human race. The science of the physiology of the animal kingdom must, like that of astronomy or any other branch of knowledge, stand upon its own merits; and it is to be regretted that it has ever been thought necessary to call in the immediate applicability of its results and the practice of medicine to justify its pursuit. Let us be candid with the public, and we shall be on more secure ground. We cannot expect men like Browning, Manning, Ruskin and their successors to be put off with anything short of the truth.

I am, Sirs, yours truly,

Fulham, Oct. 25th, 1892. WM. F. CLARKE, M.D. Lond., B.S.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Small-pox.*

THE recently published returns show that small-pox cases still continue to crop up in and around Manchester, the principal foci of the disease being Warrington and certain of the smaller Yorkshire towns which are uncomfortably near Manchester. At their last meeting the clerk to the Chorlton guardians reported the occurrence of two cases of small-pox in that union, a circumstance which naturally produced considerable uneasiness at the board, for the union seems to have been exceptionally free from this disease for a lengthened period. The guardians, however, had previously taken steps to encourage vaccination and revaccination in their district, and as the cases reported were promptly removed to the small-pox hospital it is hoped that the further spread of the disease will be prevented. If we may judge from the printed reports to be submitted to the Council at their meeting to-day, there seems to be an unfortunate hitch in completing the hospital accommodation for small-pox at Monsall. It appears that the two temporary sheds which were erected some few weeks since for the segregation of any cases of cholera that might possibly find their way hither from the Continent are

to be utilised for the treatment of small-pox. The medical officer of health, however, will not sanction the use of these sheds for that purpose until they are surrounded by a high wall and provided with separate administrative buildings, so as to render the small-pox hospital absolutely independent of the fever wards and to secure its complete isolation from them.

*The Chair of Surgery.*

It is rumoured that Professor Hare is about to resign the chair of Surgery at Owens College, unhappily on the ground of ill-health. Mr. Hare has only held the professorship for about three years, but during that period he has devoted himself assiduously to the teaching of surgery, and he certainly has won the esteem and goodwill of the great body of the students who have been members of his class. His departure from Manchester will be much regretted by a wide and increasing circle of friends, both medical and lay, amongst whom his courteous bearing and unassuming conduct have made him a general favourite.

*The Manchester Crematorium.*

On Friday last a special meeting of the advocates and supporters of cremation was held in the grounds of the Manchester Crematorium, the Duke of Westminster being present as chairman. The attendance was considerable, and there is no doubt that public opinion in these parts is being gradually influenced in favour of cremation as a means of disposing of the dead. The speeches delivered at the meeting of last week were in good taste, and will probably do much to dissipate the not unnatural prejudice against cremation which still lingers in the minds of many of our most thoughtful and public-spirited citizens.

*The Municipal Elections.*

As the 9th of November draws nearer the usual preparations become apparent for the coming contest for vacant seats in our local parliament. Ours is the largest municipal council in the kingdom outside the metropolis, and consists, since the enlargement of the city by the Act of last year, of 104 members. As is usual at election times, there is a general protestation amongst the combatants that imperial politics are to have no weight in the selection of candidates for the several vacancies; and, equally as a matter of course, every candidate whose address has hitherto been published is well known to be the nominee of one political party or another. The so-called "labour candidates" who were sent into the Council some time since with a considerable flourish of trumpets do not seem to have turned out an unqualified success, and there are indications in some of the addresses recently issued that some other expedient is about to be tried for securing the due representation of the working classes on our municipal Council. Since the recent enlargement of the Council a considerably larger proportion of medical representatives has been returned than at any previous period on record. The Council now contains five members of the medical profession; and, as these gentlemen are in every case members of the sanitary committee, it is to be hoped that their influence on the operations of that committee will be in all respects salutary. A complete list of candidates for this year's vacancies has not as yet been published; but in a city where so very much still remains to be achieved before its sanitary condition can be regarded with anything approaching complacency it is much to be desired that the number of medical members of the city Council should be still further augmented. It must be kept constantly and prominently before our representatives in the Council that the death-rate of Manchester is still exceedingly high; and I hope that, whatever may be the result of the forthcoming elections as regards the balance of political parties in the Council, every member of that body will remember that the public is getting impatient at the continuation from year to year of the present needless sacrifice of human life.

*Nottingham Medico-Chirurgical Society.*

The inaugural meeting of the ensuing winter session was held on Friday, Oct. 21st, at 8.15 P.M., Mr. R. C. Chicken, F.R.C.S., President, in the chair. Dr. P. H. Pyc-Smith, F.R.S., of Guy's Hospital, delivered an address on the Prognosis of Certain Diseases. The influences of age and sex on prognosis were considered in connexion with a large number of diseases. Chronic constitutional states often had an unfavourable influence on acute disease, this being marked in the case of chronic Bright's disease and diabetes. The importance of the gouty diathesis was, however, apt to be overrated. In conclusion the lecturer carefully examined

the prognostic import of some of the symptoms met with in the course of phthisis and typhoid fever respectively. The retarding influence of mitral stenosis or insufficiency on phthisis was fully considered. A cordial vote of thanks to the lecturer was passed, on the motion of Mr. Joseph White, seconded by Dr. Brookhouse. About fifty gentlemen were present.

*Manchester Pathological Society.*

The annual meeting of this Society was held at the Owens College on Wednesday, Oct. 12th, T. C. Railton, M.D., retiring President, in the chair. The following gentlemen were elected for the ensuing session:—President: J. S. Bury, M.D. Vice-Presidents: F. A. Southam, M.B., and W. Coates. Treasurer: W. Thorburn, B.S. Secretary: T. Harris, M.D. Committee: H. R. Hutton, M.B., T. N. Kelynack, M.B., W. Milligan, M.D., R. Patrick, M.D., C. E. Richmond, E. Roberts, R. B. Wild, M.D., and J. B. Wolstenholme. Auditors: H. Lund, M.B., and A. T. Wilkinson, M.D. After receiving the report of the treasurer and committee a considerable portion of the evening was taken up with a discussion on certain recommendations of the committee. A considerable number of card specimens were shown by Dr. Bury, Professor Delépine, Dr. Thomas Harris, Dr. Hutton, Dr. Martin, Mr. Roberts and Mr. Wright.

Oct 26th.

**BIRMINGHAM.**

(FROM OUR OWN CORRESPONDENT.)

*Health Lectures.*

THE Athletic Institute advertise a series of free health lectures. The first is to be given by Sir Andrew Clark on Saturday, the 29th, the subject being "The Religion of the Body." The chair is to be taken by Sir Walter Foster. At the annual meeting of the Birmingham and Edgbaston Debating Society on the 19th inst. Mr. Jordan Lloyd, the president, gave an address on "Some Errors of Civilisation," pointing out the nerve-strain entailed by the rate of living and its accompaniments in the present day. The facts of the discourse are indisputable, but it is not easy to find the remedy in the present constitution of society or to stem the tide of wear and tear in our surroundings.

*Hospital Sunday.*

The return of this anniversary on the 30th inst. brings reflections as to the growth and maintenance of the fund raised on the occasion. For years past the amount subscribed has been declining. The rival Hospital Saturday collection has diminished seriously that of the more sacred day, owing to the splendid organisation and method of collecting in workshops and factories. The eloquence of the divine can hardly compete with the activity of the commercial man, whose opportunities of obtaining contributions are of a more practical kind. The growth of Hospital Sunday appears to have followed that of most institutions in reaching an acme of development and then declining. "This year the collections go to the General Hospital, and in the face of the earnest appeal for funds made by that charity it is hoped that a large sum will be realised.

*The Mason College.*

This College, with which is incorporated the Queen's Faculty of Medicine as representing the former medical school of Queen's College, has issued an elaborate and complete calendar. The information given is carefully and exactly worked out, and a varied programme of the different faculties enables any seeker for knowledge of the teaching details to find readily what is wanted. The subject of a midland university in connexion with this College has lately been receiving attention and finds favour in every quarter. There are arguments which would make such a scheme desirable in the interests of education in the midland counties. Meantime the requirements of medical teaching, at least, are provided for in a manner calculated to compare favourably with any other school in the kingdom.

*Crime in Birmingham.*

The chief constable's report for the year ending Sept. 29th has just been issued. The return consists of two tables, the first relating to offences indictable at quarter sessions and assizes; 965 crimes were committed, as against 950 last year and 901 in the year 1890. The second class relates to the

magistrate's jurisdiction. Proceedings were taken against 14,795 persons, as compared with 14,043 in the previous year and 13,447 in 1890. Persons proceeded against for drunkenness show an increase of 273. It is true that the extension of the municipal boundaries makes some difference in the figures, but the evidence does not tend to show that crime is retrogressive in this best-governed city.

Oct. 25th.

**NORTHERN COUNTIES NOTES.**

(FROM OUR OWN CORRESPONDENTS.)

*Memorial to the late Albany and John Hancock.*

A TABLET to the memory of the late Albany and John Hancock has just been placed in the entrance hall of the Natural History Museum, Newcastle, by a number of their friends and admirers in recognition of their invaluable work of research in natural history. The tablet, which is a very handsome work of art in Sicilian marble, with a frame of Derbyshire alabaster, has been designed by Mr. Joseph Craggs, of this city, and bears the following inscription:—"To the memory of the Brothers Albany Hancock and John Hancock. Albany was distinguished for his anatomical researches among the invertebrata and received in 1858 the gold medal of the Royal Society for his investigations of the brachiopoda. John was celebrated as an ornithologist and for the lifelike character he gave to the birds which he preserved. It was through his personal influence that funds were obtained for the erection of this building, on the completion of which he presented his ornithological collection to the Natural History Society."

*Tynemouth.*

The report of the chief constable for Tynemouth for the past year has been published, and without some explanation it would in some respects be an alarming document. It shows that 1269 males and 372 females had been charged with drunkenness—a heavy record for a town with a population under 50,000 were it not also shown that one-half were seamen who occasionally visit the port and visitors who come to Tynemouth on Sundays and holidays. The number of public-houses in the borough had been reduced during the year by six. With reference to persons arriving from cholera-infected ports, the *Newcastle Courant* says that the medical officer of the borough has complained of the delay that takes place after they come on shore before he is informed by the Sanitary Authority of their arrival. Each communication it seems has to pass through four different parties' hands before the medical officer receives it, three and four days thus elapsing, so it is suggested that in this very important matter some more simple and direct mode of procedure might well be adopted. The Tynemouth Corporation have decided to utilise the present infectious diseases hospital, should it be necessary, for cholera cases. For other infectious diseases they have decided to erect a new hospital, and are negotiating with the Duke of Northumberland's agent for a suitable piece of land in the outskirts of the borough.

*Alnwick Infirmary.*

The annual general meeting of the governors of the Alnwick Infirmary was held last week, Earl Percy presiding; 538 patients were treated during the year, and the financial state of the institution was good, the year closing with a substantial balance in hand.

*The proposed Infectious Diseases Hospital at Keighley.*

Messrs. Marshall and Dick of this city have been awarded the first premium for their plans for the Borough of Keighley (Yorkshire) Infectious Hospital. The competition was open to architects from all parts, and about thirty plans were sent in. The hospital has been designed to accommodate thirty beds, and separate wards of ten beds each have been planned for small-pox, typhoid fever and scarlet fever, besides the usual administrative department and residences for matron, nurses &c.

*Death of the Deputy Coroner for South Northumberland.*

Mr. Wm. Brewis Elsdon, Deputy Coroner for South Northumberland, died last week from acute pneumonia after a very short illness.

*Deaths of Medical Men.*

Dr. Andrew Gibb Russell, J.P., of Harrogate died at his residence in that town on Wednesday last after a short illness.—The death is also announced of Mr. R. P. Edger, of Helton-le-Hole, county Durham, in his ninety-fourth year.

Mr. Edger qualified as far back as 1823. I hope in my next letter to say more about his career.

#### *Odds and Ends.*

The annual dinner of the Newcastle Clinical Society took place last Thursday, and it passed off very successfully. Mr. Galloway of Bighton Banks presided.—Our medical officer of health states that for the fortnight ending the 15th sixty-seven cases of infectious disease were notified as occurring in Newcastle; of these, fifty-seven were cases of scarlet fever.—It is stated, as showing the pressing demand for chloride of lime during the late cholera alarm, that a few weeks ago it rose to £15 per ton, and although there is still a larger inquiry than usual for it and the manufacturers' stocks are small, the price has now fallen below £8 per ton on the Tyne.—Dr. Scott Purves, instructor of the ambulance class at Long Houghton, has received a presentation of a handsome piece of plate from the members of the class.—An earthquake tremor was experienced in Newcastle on Sunday night last.

Newcastle-on-Tyne, Oct. 28th,

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *General Council of the University of Edinburgh.*

THE statutory half-yearly meeting of the General Council of the University of Edinburgh will be held in the University on Friday, the 28th, at 3 P.M. At this meeting the reports of the business committee, the ordinances committee and the finance committee will be considered in addition to other routine business. These reports and their fate at the Council will be referred to in detail after the meeting of the Council.

### *New Municipal Bill for Edinburgh.*

A new Municipal Bill has been under discussion in the town council for some time. At a special meeting held in the beginning of this week several important provisions in the proposed Bill were considered and approved or left for further report and consideration. One of these was a clause providing for the removal of the slaughter-houses and cattle market beyond the city's boundary. This was remitted to the Lord Provost's committee. The next set of proposals bearing upon city improvements included proposals to open up and improve the property immediately adjoining the University new buildings. This especially referred to the property to the east of the University, which is in an indifferent condition, and from its proximity to the University mars considerably its architectural effect. The acquisition of this property by the town and its conversion into an open space would be a great improvement to the locality as a whole, as well as to the University buildings and the Students' Union. The proposals were opposed by a few of the Council, on the ground that it was done entirely for the sake of the University. This view, however, was not taken by many, and the proposals were carried by a large majority. The next proposals dealt with the acquisition of sites and the erection of refuse destructors. Permission is sought for the erection of four destructors within the city. This also met with a good deal of opposition, it being asserted that the destructors would be a nuisance in the localities in which they would be erected; this was denied by various members, including the Lord Provost, who referred to the Bradford destructors and said that they were worked without nuisance. Of course the carting of refuse would always be more or less of a nuisance, but it was that at present. These proposals were also carried.

### *Opening of the Royal Medical Society, Edinburgh.*

On Friday evening of last week the new session of this Society was inaugurated by an address from Dr. Lauder Brunton. The chair was occupied by the senior President, Dr. Miles, and the lecturer was well received.

### *Health of Edinburgh.*

The mortality last week was 123, making the death-rate 24 per 1000. Diseases of the chest caused 64 deaths and zymotic diseases 37, of which 27 were due to measles. The intimations were: Typhus fever, 1; typhoid fever, 4; diphtheria, 9; scarlet fever, 66; and measles, 296.

### *Pauper Infirmaries and Medical Students.*

Professor Ogston, in performing the ceremony of opening a new infirmary for the Oldmachar Poorhouse, Aberdeen,

spoke of the benefit which would accrue to the students, to the guardians of the poor and to the paupers themselves if the hospital were open for clinical purposes to students of medicine. Dr. Ogston continued: "I think I am quite correct in saying that the introduction of students into the wards will be found to have a still further humanising effect upon the institution; for the more advanced and more intelligent students, who would be those selected, are really the most admirable critics and suggestors in regard to all that is most beneficial in such an institution, and their attitude towards the poor becomes speedily of itself an extremely humanitarian agency." The chairman promised that Dr. Ogston's suggestions should have the consideration of the board.

### *Health of Aberdeen.*

Last week there were notified 388 cases of measles, 33 of scarlet fever, 3 of diphtheria, 1 of typhus fever, 3 of whooping-cough, and 7 of erysipelas (a total of 435 cases), being a decrease of 10 as compared with the previous week.

### *Aberdeen University Extension Scheme.*

At a meeting of the University Court held this week, after a long discussion, in the course of which several motions were proposed, that of the Lord Rector was carried by a large majority. His motion was that they proceed at once with the extension of the north wing and the front wing at Marischal College, and with the erection of a new wing for natural philosophy at King's College, and that the architect be instructed to bring up detailed plans for the new graduation hall and students' rooms and the addition to the anatomical department in Marischal College.

### *Northern District Asylum, Inverness.*

On Tuesday the vacancy in the superintendentship of this asylum, caused by the death of Dr. Aitken, was filled by the appointment of Dr. Cumming Mackenzie, assistant superintendent of Northumberland County Asylum at Morpeth.

### *Death of Dr. Cran of Ballater.*

Dr. Robert Cran (Ballater, Aberdeenshire) died suddenly after a few hours' illness at Wemyss Bay on Sunday, the 23rd inst. Dr. Cran had spent most of his professional life in Assam and had been but four years in practice in Ballater. At the time of his death he had been married only twelve days and was on his honeymoon.

### *Death of an Aberdeen Graduate in Egypt.*

On Monday the sad news reached Aberdeen that Dr. William Smith Robertson died that morning at Port Said, where he held the appointment of senior medical officer in the Egyptian Government hospital. Dr. Robertson graduated at the University of Aberdeen in 1877. He was only thirty-seven years of age and leaves a widow, who sailed for Port Said last week to join her husband.

Oct. 25th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Royal College of Surgeons.*

THE following address was presented to his Excellency last week:—

TO HIS EXCELLENCY LORD HOUGHTON, LORD-LIEUTENANT-GENERAL AND GENERAL GOVERNOR OF IRELAND.

MAY IT PLEASE YOUR EXCELLENCY.—We, the President, Vice-President, and Councillors of the Royal College of Surgeons in Ireland, desire to offer to your Excellency our most respectful congratulations upon the occasion of your Excellency's assumption of the high office which Her Majesty has entrusted to you. We beg to assure your Excellency that the College which we represent has, since its incorporation more than one hundred years ago by Her Majesty's Royal decessor, King George the Third, been animated by sentiments of loyal devotion to the Crown and Government of the United Kingdom, by an anxious desire for the maintenance of prosperity and good order of the country, and by an earnest wish efficiently to discharge, by sound education and searching examination, the duties imposed upon it more than one hundred years ago in its original charter, to provide "a sufficient number of properly educated surgeons, as well for the service of the public in general as for that of our army and navy." The important public functions which were confided to this College by its charters have been discharged faithfully, and, we venture to hope, with success. Your Excellency's inherited, as also self-earned, claims to high literary distinction will enable you to estimate at its proper value the fact that this College, from its foundation up to the present moment, never has admitted to even its lowest qualification anyone who had not previously passed an examination in Arts; and its early recognition of the importance to the public weal of a knowledge of sanitary science may be inferred from the fact that some fifty years ago it instituted its Professorship of Hygiene. We trust that your Excellency will be pleased,

by visiting our College, and by inspection of its various departments, to satisfy yourself that it is in a condition to fulfil satisfactorily its duties to Her Majesty and the public.

The prizes obtained by students, at the schools of surgery during the session 1891-92 will be awarded by Mr. Edward Hamilton, President of the College, at the opening of the winter session on Nov. 1st.

#### Royal College of Physicians.

The portrait of the founder of the College, Dr. John Stearne, S.F.T.C.D., presented by Dr. Samuel Gordon, was referred to briefly in these columns last week. The picture, which is a half-length portrait, is a copy by Mr. Catterson Smith, R.H.A., of the original in the possession of the University of Dublin. It represents the deceased in the scarlet gown of a doctor and a voluminous wig of the Queen Anne period, and must be regarded as a worthy addition to the portraits of distinguished Fellows possessed by the College.

#### Rotunda Lying-in Hospital.

An appeal has been made for funds to enable the governors to place the hospital in a condition of thorough efficiency worthy of its established and world-wide character. About £10,000 will be required to carry out the necessary alterations, and of this some £5000 have already been collected. It is proposed to erect a new building for the treatment of diseases peculiar to women; to provide suitable day and night accommodation for nurses, probationers and female students; to erect a lift to convey helpless patients to the wards and to provide lavatories, bath-rooms &c. The sum now required is not so much but that the charitable public could easily supply the necessary amount, and I hope that they will do so, for the institution is well worked and a credit to any city. I do not envy the feelings of those members of the corporation who refused the trifling grant of £250 to the hospital, and trust their act of intolerance may stimulate the charitable people of Dublin to aid and assist to the utmost an institution so worthy of support as the Rotunda Lying-in Hospital.

#### The Legality of Bequests to Medical Attendants.

IN England one hears occasionally of a professional brother having his grief at the loss of a profitable patient by death attenuated by a more or less important legacy bequeathed him by the deceased. In France, such a compensation is, in most cases, out of the question, for, by the terms of Provision 909 of the Civil Code, a practitioner is debarred from inheriting from a patient whom he attended during his last fatal illness, provided the will containing the bequest was made during the said illness. It was, however, ruled by the Court of Cassation in 1834 that the above law did not apply to a doctor called merely in consultation. It is therefore necessary, in order to establish the nullity of a testamentary bequest made in favour of a member of our hard-worked profession, to prove—(a) that the would-be legatee was actually treating the patient; (b) that the bequest was made during the course of the disease, which (c) proved fatal. A short time ago the heirs of a gentleman were cited before the tribunal of Angoulême, at the instance of Dr. Fournier, to show cause why a legacy of 21,500 francs should not be paid to the doctor. Fortunately for our *confrère* he was able to show that, as he only replaced for a time the deceased's regular attendant, the validity of the bequest could not be impugned. I may mention that chemists, *sage-femmes*, and indeed any unqualified person who undertakes the care of a malady which proves fatal, enter within the scope of the above law. In the case, however, of a *sage-femme* in whose house a lady died the validity of a bequest made in favour of the midwife was upheld, it having been proved that a medical man called in was responsible for the treatment pursued.

#### Precautions against the Spread of Tuberculosis.

The Sanitary Commission of the 10th Arrondissement, which comprises the populous district radiating from the St. Louis Hospital, have, with the view of stemming the tide of tuberculosis, proposed the following measures: That the dwellings and clothing of tuberculous patients be submitted to the same process of disinfection as in the case of

other contagious diseases; that all railway compartments, cabs and omnibuses, or at least the floors of such vehicles, be disinfected daily with a solution of zinc chloride. Manners as regards what may be dubbed public-expectoration are disagreeably free amongst this otherwise very polite people, and this consideration, together with the undoubted contagiousness of tuberculosis, renders the purification of public conveyances very necessary. The Parisian has an unwholesome dread of fresh air when travelling, and the tyranny exercised by the lively but stuffy Gaul in the matter of sealed windows is well known to all British tourists.

#### A Congratulatory Banquet.

On Thursday last Dr. Pietra Santa, editor of the *Journal d'Hygiène*, was entertained at dinner at the Grand Hôtel by a large gathering of admiring colleagues, the occasion being the fiftieth anniversary of his appearance on the world's stage as a doctor of medicine. Dr. Pietra Santa's fearless advocacy of sanitary reforms during the many years he has directed his valuable journal rendered him worthy of such a compliment, the remembrance of which will be made more durable by the presentation of a handsome gold chronometer and chain. Numerous English *confrères* were amongst the subscribers. Another veteran in sanitary science was present in the person of Dr. Benjamin Ward Richardson, who triumphantly accomplished an unusual feat for a Briton—viz., delivering an admirable discourse in French. The opportunity was seized for commemorating the visit of Dr. Richardson to Paris in June last at the head of the Association of Sanitary Inspectors of Great Britain. With this intent the Société d'Hygiène offered Dr. Richardson, through Dr. Brémond as their mouthpiece, their bronze medal. Everybody—and their name is legion—acquainted with Dr. Richardson's lifelong efforts in the cause of public and personal health will rejoice at the great honour paid him by such a distinguished body as the Société d'Hygiène.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### The Cholera in Russian Poland.

THE Prussian Commissioner for the basin of the Vistula states that there were 54 cholera cases and 12 deaths in Warsaw between the 13th inst. exclusive and the 18th exclusive, 45 and 24 in the governmental district of Kielce between the 9th and the 14th, 74 and 37 in that of Radom between the 7th and the 14th, 235 and 128 in that of Lublin between the 12th and the 16th, and 132 and 46 in that of Siedlee between the 11th and the 16th.

#### Guttmann's Reichs-Medizinal-Kalender.

The first part of Guttmann's *Reichs-Medizinal-Kalender* (*Medical Calendar for the German Empire*) contains an essay by Professor von Pettenkofer on the Hygienic Lighting of Dwellings. The second part contains a list of all the German doctors, a list of the officers of the ambulance corps according to rank and seniority, and statistics concerning medical men, apothecaries' shops, hospitals &c.

#### Appointments &c.

Dr. August Wagenmann of Heidelberg has been appointed Professor of Ophthalmology at Jena. He is a frequent contributor to *Graefe's Archiv für Ophthalmologie*.—Dr. Krehl of Leipzig has been appointed Professor and Director of the Medical Policlinic at Jena. His special field is heart disease. He has published most of his writings in the *Archiv für Physiologie* and in the *Archiv für klinische Medizin*. He is only thirty-one.

Professor Bechmann of Giessen has been appointed Professor of Pharmacy and Director of the Pharmaceutical Institute at Erlangen.

The sentence of Dr. M. Wiederhold, head of a private hospital at Wilhelmshöhe near Kassel, to three months' imprisonment, for whipping one of his lady patients, has been commuted by the Emperor into the much less disgraceful one of three months' confinement in a fortress. This act of grace is said to have been actuated by the circumstance that the convict belongs to the military profession as an assistant doctor of the first class.

Berlin, Oct. 25th.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*The Anglo-American Medical Association.*

THE first meeting of the Anglo-American Medical Association took place on Oct. 14th, and was very well attended by numerous English and American physicians, who are now in Vienna continuing medical study at the General Hospital in various special branches of medicine. The meetings will now be held more frequently than in former years, and it is intended to arrange lectures from time to time to keep the members informed of the progress of medicine in their native tongue.

*A Poison prepared from Fresh Egg Albumen.*

At the last meeting of the Vienna Society of Physicians Professor Max Gruber showed some experiments on animals (guinea-pigs and rabbits) with a substance obtained from fresh egg albumen of chicken. The egg albumen is shaken with pure water and then treated with absolute alcohol. The precipitate thus obtained, treated with water again for some time, yields a yellowish alkaline solution which proves to be highly poisonous, exhibiting a curare-like action if injected in animals. If small quantities of five cubic centimetres are injected into the peritoneal cavity of guinea-pigs, after a short period of excitation paralysis of the voluntary muscles, with fibrillary contractions of the muscles, is produced, the frequency of respiration becomes lowered, but after some hours the animal recovers again; but if fifteen cubic centimetres were injected complete paralysis of the voluntary muscles would set in within two minutes, and after six to nine minutes the animal died, as if under the action of curare. The poison seems to be an albuminous body, similar to some of the snake poisons; it loses its poisonous action by being exposed for some days to the influence of air and light. The poisonous solution does not coagulate if cooked in the fresh state, but it coagulates readily by heat if the solution has become some days old.

*Inhibition of Growth in Sheep after Thyroidectomy.*

Dr. von Eiselsberg, assistant of Professor Billroth, in continuing his researches on the influence of the extirpation of the thyroid gland on the growth of animals, has found considerable differences in the development of sheep after thyroidectomy. In two lambs soon after birth the thyroid gland had been extirpated, and now, after eight months, the animals showed the following differences from two other lambs of the same age: The bodily weight was only 10 and 14 kilogrammes in the operated animals, while it was 35 and 27 kilogrammes in those not operated upon. The hind part of the head and the abdomen of those operated on are considerably enlarged and gives to them a peculiar appearance, their tails are only rudimentarily developed, their testicles are atrophied, their fleece is bad, their intelligence is lower than in the normal animals and they are suffering from chronic bronchial catarrh with viscous secretion similar to that which is often observed to occur in human beings after thyroidectomy. Various therapeutical experiments will shortly be made on these animals which were demonstrated at the last meeting of the Vienna Medical Society.

Vienna, Oct. 27th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

*The Medical Profession in Australia.*

A VERY interesting State paper has recently been issued from the Government Statists' office, dealing with the professions, trades and occupations of the people of Victoria as set forth in the census returns of 1891. In the last decade the population of Victoria increased by a little over a quarter of a million, being now 1,140,000. It is instructive to note in what walks of life the increase has been most marked. To understand the subject aright it must be remembered that the last decade was remarkable for the large amount of money borrowed from British investors by the Government of the colony; for a consequent abnormal activity in industrial pursuits; and for an outburst of speculation in comparison with which the South Sea Bubble and the railway mania were mere emotions. Bearing these

facts in mind it is not surprising that there has been a considerable increase in the number of persons described as of "independent means" and of "no occupation"—the class "who toil not, neither do they spin." The number of artisans and mechanics has more than doubled, while the agricultural and pastoral community has made little or no increase. The mining population has diminished by a third, while the devotees of literature and science have increased their numbers by a third. Clergymen, lawyers and doctors have more than doubled their numbers. Under the heading "Medical Profession" are included "physicians, surgeons and druggists." In 1881 there were 1595 such persons in the colony. In 1891 the number had increased to 3474. In 1881 the proportion to the population was 1 to 540; in 1891 it was 1 to 328. That there has been a large increase in druggists and quacks is undoubted, but there has also been an abnormal increase in the number of qualified medical practitioners, so that now the number of doctors in the colony is out of all proportion to the population. Victoria, and in fact all Australia, as a field for medical emigration is played out. The large cities are overrun with medical men out of employment, anxious to grasp at anything that offers. Whereas only a few years ago there were one or two applications for appointments to country hospitals, there are now dozens of applicants for the post of resident surgeon to even the most out-of-the-way country institutions. It is a matter for regret that the rising generation despite the trades and occupations of their fathers when these occupations entail earning their bread by the sweat of their brow, and they unfortunately all aspire to enter a profession where they can wear a black coat and put on the gentleman by Act of Parliament. This apotheosis of snobbery is a very sad phase of our civilisation.

*The Treatment of Club-foot.*

At a recent meeting of the Medical Society of Melbourne Mr. G. A. Syme, F.R.C.S. Eng., read a thoughtful paper on the Causation and Treatment of Club-foot. His researches had led him to believe, with Parker, Eschricht and others, that "club-foot is an arrest of development—the permanence of a certain stage in the evolution of the lower limbs," and he brought evidence to show that this arrest of development was due to compression of the fœtus in the womb owing to largeness of size, presence of twins or deficiency of liquor amnii. Setting out with these views, Mr. Syme advocated the treatment of the whole limb and not merely the foot. Division of tendons and ligaments might reduce the deformity, but the improved position was only transitory. He had adopted and improved on Mr. T. N. FitzGerald's treatment as described in the records of the last Intercolonial Congress. His method is to divide freely the ligaments of the astragalo-scapoid joint and to forcibly twist the foot into position. Then the bones and cartilages are divided and the divided structures are crushed and moulded into position, so that when union takes place the position of the foot is permanent and the foot is strong and solid. This was the great point in the operation, and so far as the foot is concerned the results are splendid. Mr. Syme did not think that one need be very particular as to the exact bones divided or the direction of the chisel, provided they are separated on the inside and well broken up, compressed and approximated on the outer side. The last proceeding was of great importance, the union and ossification of the crushed fragments firmly holding the foot in its improved position. Mr. Syme then went on to say: "Admirable as this operation is, however, I venture to think it often requires to be combined with further procedures. By it the shape of the foot and its position in relation to the leg can be completely rectified and the patient can stand to be photographed, so that the result excites admiration, but when the child walks it will often be found that he or she still does so with a peculiar gait, turning in the toes. To obviate this I think it is advisable, as before observed, to divide the tibia and rotate the whole foot out, and very possibly it will be necessary to divide the femur as well. Ogston divided the tibia and fibula, without interfering with the foot at all, and says 'the results were as satisfactory as those he obtained by Lund's operation,' but 'some bayonet-shaped deformity of the leg and ankle' resulted, 'produced by the great rotation outwards of the foot.' I think that by combining the procedures less interference is required in each. The inversion and part of the adduction can be rectified by Mr. FitzGerald's method, the further adduction and inward rotation by division of the tibia, which yet need not be rotated so far as to produce any

'bayonet-shaped' deformity. If this be not sufficient, the femur can be divided, and the limb slightly rotated out. If the whole rotation out be obtained by division of the femur only, an awkward deformity may be produced at the knee, the patella looking outward."—Mr. T. N. FitzGerald took part in the discussion which followed, and warmly congratulated Mr. Syme on the improvement he had made in the operation and on the admirable results he had produced.

## Obituary.

### CONWAY EVANS, M.D. LOND.

OCTOBER has been a black month, and many *dies atri* already blacken the calendar. Dr. Conway Evans had of late complained much of dyspnoea and cardiac weakness, but did not give up work until some two months ago, when he consulted Mr. Gowan of Stanmore and Dr. Wilks, who found he was suffering from Bright's disease, heart trouble and dropsy. He obstinately refused all medicines, and died, at the age of sixty-two, on Oct. 18th, at his residence, Hyde Cottage, The Hyde, Hendon. He was buried last Saturday at his birthplace, Pontrhydyrun, in Monmouthshire. He was born in 1830; his father was the Rev. D. D. Evans, a Nonconformist minister, and his mother's maiden name being Conway, he was given the name of David Conway Evans. As a boy he was sent to Mill Hill School, where he rapidly rose to the highest place. He was afterwards apprenticed (as was the custom in those days) to Mr. Lawrence, surgeon, of Pontypool. He entered as a medical student at King's College in October, 1849, where he was remarkable for his industry and brilliant talents and where he obtained several honours and distinctions. He was appointed house physician for the winter session of 1854-5, and the manner in which he performed the duties of his office may be estimated by a reference to the preface to the Clinical Lectures of the late Dr. Todd, in which the fullest and warmest acknowledgment is made of Dr. Conway Evans' valuable aid in making clinical reports and important analyses in Dr. Todd's cases in King's College Hospital. He graduated at the University of London, took his M.B. and the scholarship and gold medal in medicine in 1855, and his M.D. in 1857, in which year he was elected physician to the public dispensary; he was also for many years assistant physician to King's College Hospital, where he was a very successful teacher and a great favourite with the students. He was pathological registrar and curator of the Pathological Museum from 1865 to 1868, and showed many interesting exhibits to the Pathological Society. Dr. Conway Evans also filled the position of medical adviser to the firm of W. H. Smith and Son in a manner that obtained for him the gratitude and respect of all with whom he thus became associated. He was appointed medical officer to the Strand District Board of Works on the formation of that board in 1855. Here he found work exactly suited to his taste, and he soon became a typical medical officer of health. His annual reports are models of what such reports should be, and are specially referred to and commended by Mr. Firth in his great work on the municipal government of London. The district has more people in proportion to houses than any other and the population is less migratory; yet Dr. Evans made it remarkable for the excellence of its sanitary arrangements, its freedom from epidemic and contagious disease and its comparatively low death-rate. During the last cholera epidemic of 1866, no district was better organised, and the deaths from cholera were 23 only, as against 111 in 1854 and 156 in 1849. To show their high appreciation of his work in general, the board doubled his salary at once without a dissentient voice, and for his work during the cholera epidemic of 1866, they voted a special gratuity of £150. As physician to the Lincoln's-inn public dispensary Dr. Evans gave to every poor patient the same time and careful study that he gave to a rich one, and, although he professed an utter scepticism as to drugs, his practice indicated a strong belief in them. Such inconsistency of conduct with creed is, fortunately for us all, not uncommon in this as in other matters; but, unfortunately for him and for us, Conway Evans was consistent in his own case and in his last illness, for he

persistently refused to take medicines that would certainly have given him relief and possibly prolonged his days. His quickness and accuracy in diagnosis were marvellous; but no one was more painstaking in the investigation of a case in which there might be room for doubt. One glance of his would often reveal to him the patient's disease. In this he resembled the late Dr. Addison of Guy's, whose eye, like a speculum, brought hidden things to light. Conway Evans was a man of various tastes, accomplishments, and pursuits; he loved country life and was always happy when farming, gardening or building; he was also fond of collecting valuable pictures and books. When the old Hyde cottage was burnt down in November, 1886, most if not all of these were destroyed, and he thought his last illness originated in the shock he then received and the long night of exposure to the cold, damp air. Conway Evans's mind was original, independent and thoroughly honest. His work was thorough and he held strong views and opinions, from which he never swerved; he had little of the *suaviter* and less of the conventional; but he did much quiet, useful work and helped many who were in trouble and did his duty without fear or favour; "because right is right, he followed right, in scorn of consequence." In short, he was a very uncommon man, and the profession and the poor will be all the poorer without him. He will be sadly missed by his intimate friends and pupils, all of whom will *feel*—if they do not say of him—what Wordsworth said of one he dearly loved—"but Conway's in his grave, and oh, the difference to me!" A sterling honest man and a most able and thoughtful physician bound by no man's special views has passed from our midst.

### F. J. BURGE, M.R.C.S. ENG., L.S.A.

WE regret to have to announce the death of Mr. F. J. Burge at Hastings, on the 13th ult. The circumstances connected with the career and work of the deceased gentleman merit, however, more than a brief reference to the event. As one of the original medical officers of health for an important suburb of London, his labours for the promotion of the public well-being in sanitary matters ought not to be suffered to be forgotten. Mr. Burge studied at St. George's Hospital and obtained his surgical diploma in 1843, after having successfully passed the examination at the Hall at Blackfriars. He commenced practice in the first instance at Blagden, Somersetshire, but subsequently removed to Shepherd's Bush, where he soon secured a numerous  *clientèle* . The work for which he will be most remembered, however, was that connected with the duties of his appointment as medical officer of health for Fulham and Hammer-smith, which post he held for twenty years, and from which he retired on a pension. In this sphere of activity he distinguished himself by his zeal and activity, at a time when sanitation had not attained the degree of public estimation it has now secured. In his twentieth annual report to the Board of Works for the Fulham district, dated May 24th, 1876, Mr. Burge gives a summary of the work accomplished under his direction and advice during the period of his tenure of office. Moreover, for the discharge of the duties belonging to it he did not fail to qualify himself by the study of technical matters pertaining to his charge. He took great interest in the analysis of water and food under Mr. Crookes' tuition, and worked many an hour in his laboratory or with his microscope after a hard day's general practice. Whilst his daily attention was given to the routine work of his district, he did not overlook matters which at that time were regarded as outside his special province. Thus he gave attention to the condition of surface wells, to the necessity for the construction of good sewers in connexion with the main drainage scheme, the importance of isolation in infectious cases, the ventilation of bakehouses, and many other subjects of public sanitary interest. He was ever a willing helper in the promotion of any agency which he regarded as likely to further the physical and moral interests of the people. On retiring from practice in 1877 Mr. Burge went to reside at Wraybury, but afterwards removed to Hastings, though he still maintained an active interest in local affairs. He was twice married, the issue of the first wife being three sons and one daughter. One son, who is at present in practice as a physician at Shanghai, and the daughter alone survive.

## ROBERT PHILIPSON EDGER, L.S.A.

At the great age of ninety-four the subject of this notice passed away on the 21st ult., at Hetton-le-Hole, where he had lived and practised for sixty-six years. Mr. Edger, who obtained his qualifying certificate from the Apothecaries' Hall in 1823, belonged to a family of surgeons, his father and three brothers having followed the profession of medicine in the north of England. In 1826 he obtained the appointment of surgeon to the Hetton Coal Company and for more than fifty years discharged the duties of that office with general acceptance. He was ever foremost in the promotion of movements of public utility in the district. Amongst his endeavours to advance the physical well-being of his neighbours may be mentioned the large share he took in establishing a company for the supply of pure water. He also took great interest in building societies, feeling such associations to be active agencies for the fostering of prudent habits in working people and for promoting the encouragement of the provision of healthy dwellings. As an able practitioner, as a courteous and upright man and a worthy citizen, the memory of Mr. Edger will not soon be forgotten.

## ROYAL COLLEGE OF PHYSICIANS.

THE quarterly Comitia of the Fellows of the College of Physicians was held on the 27th inst., the President, Sir A. Clark, Bart., in the chair. Eight gentlemen were admitted Members of the College, and licences were granted to those who had passed the recent examination.

The College seal was affixed to a copy of the new edition of the by-laws.

The executors of the late Dr. Ditchfield having presented a further collection of engravings, the property of that gentleman, the thanks of the College were accorded for the gift on the motion of the Senior Censor, seconded by the second Censor.

The annual accounts of the College and the quarterly report of the Finance Committee were received and adopted.

Two Reports from the Committee of Management were read and adopted. They embraced the recognition of Rainhill Asylum as a place of study for the Final Examination, the recognition of the courses of instruction in Public Health at St. Bartholomew's Hospital and at the Bristol Medical College as fulfilling the requirements for the Diploma of Public Health, and the recognition of certain schools of science as places of instruction in the subjects of the First Examination.

A report from the Laboratories Committee was also adopted.

Dr. W. M. Ord and Dr. Pye-Smith were re-elected members of the Management and Laboratories Committees respectively.

On the motion of Dr. Allchin it was resolved to add to the by-law clxxvi. a clause embodying the resolution passed at the last meeting of the College with respect to the sale or purchase of practices by Fellows or Members.

The quarterly report of the Examiners for the Licence was adopted on the motion of Dr. F. T. Roberts, seconded by Dr. N. Moore.

## Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, IRELAND: CONJOINT SCHEME.—The following have passed the Third Professional Examination:—

J. W. Burne, E. Cairns, J. Campbell, P. J. D. Coen, T. C. Cummins, J. E. Dobbs, Thos. Fagan, W. B. Felton, R. C. Fisher, J. Fleming, G. L. Freeman, C. Kapp, J. P. Martin, D. Molyneux, J. A. Morgan, T. M. Morton, F. Nolans, J. J. O'Donnell, C. Skelly, E. W. Smith.  
Second Professional Examination.—In addition to the list already published, the following have been allowed this examination:—G. E. Calthness, E. A. Chartres, J. F. Smyth.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed an examination in the subjects indicated:—

Surgery.—J. B. Bate, Bristol; J. C. Bawden, Liverpool; C. H. Broadhurst and E. D. Cox, St. Mary's Hospital; A. D. Davies, London Hospital; H. T. Dufton Cambridge University and St. Bartholomew's Hospital; J. L. Iredale, Yorkshire College, Leeds; H. R. Mortis, Charing-cross Hospital; S. Wilkinson, Liverpool.

Medicine, Forensic Medicine and Midwifery.—C. D. Cardinal, St. Bartholomew's Hospital; N. Elvington, St. George's Hospital; W. S. Mercer, Charing-cross Hospital; H. W. Oborn, St. Thomas's Hospital.  
Medicine and Forensic Medicine.—J. C. Bawden, Liverpool.  
Medicine and Midwifery.—H. E. Cooper and C. W. H. Newington; St. Bartholomew's Hospital; J. F. Stockwell, St. Mary's Hospital; E. Williams, London Hospital.  
Forensic Medicine.—W. R. Clarke, Belfast.  
Midwifery.—W. A. Jones, Bristol; F. Melandri, University of Bologna; B. Saul, Charing-cross Hospital.

To Messrs. Bate, Broadhurst, Clarke, Iredale, Melandri, Mercer, Oborn and Wilkinson was granted the diploma of the Society entitling them to practise Medicine, Surgery and Midwifery.

ST. JOHN AMBULANCE ASSOCIATION.—On the 22nd inst. the medallions and certificates won by the successful students attached to the No. 2 district of the St. John Ambulance Association were presented by the Lady Mayoress at the Mansion House. After the presentation the Lord Mayor made a few remarks on the value of the first aid movement, and Sir V. Kennet-Barrington congratulated the members of the organisation on the success and utility of its labours.

FIRE AT AN ANATOMICAL MUSEUM.—The anatomical collections of the Karolin Institute in Stockholm have been seriously damaged by fire. The valuable series of Swedish skulls and skeletons is completely destroyed. By the strenuous exertions of the firemen some of the other collections were saved, including the embryological series. There was, however, very serious damage done to the valuable collection of Egyptian and Lapp skulls made by Professor Retzius.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The annual meeting was held at the Royal Kent Dispensary, Greenwich, on the 7th inst., H. W. Roberts, Esq., President, being in the chair. The following gentlemen were elected as officers of the Society for the session 1892-93:—President: George Newton Pitt, M.A., M.D. Cantab. Vice-Presidents: John MacGavin, L.R.C.P. Edin., and Peter Cooper, M.R.C.S. Council: A. Stewart Brown, F.R.C.S. Edin.; Wm. Arbuthnot Lane, M.B., B.S. Lond.; John Gordon Mainwaring, M.R.C.S.; Williams Nicholson, M.D. Edin.; Charles Jas. Parke, M.R.C.S.; F. S. Smyth, L.R.C.P. Edin.; Francis T. Tayler, M.B. Lond. Treasurer: Prior Purvis, M.D. Lond. Secretary: Ernest Clarke, M.D., B.S. Lond. Librarian: John MacGavin, L.R.C.P. Edin.

SCHOOLS OF SURGERY, ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the prize list for the session 1891-92:—Junior Descriptive Anatomy: G. E. J. A. Robinson, First Prize (£3) and Medal; C. B. Martin, Second Prize (£1) and Certificate. Senior Descriptive Anatomy: E. J. Moore, First Prize (£3) and Medal; E. A. Meeke, Second Prize (£1) and Certificate. Practical Anatomy, First Year: J. R. Sinton, First Prize (£3) and Medal; F. J. Purcell, Second Prize (£1) and Certificate. Practical Anatomy, Second Year: A. Leventon, First Prize (£3) and Medal; E. J. Moore, Second Prize (£1) and Certificate. Practical Anatomy, Third Year: H. R. Sweeney, First Prize (£3) and Medal; L. F. Corbet, Second Prize (£1) and Certificate. Practice of Medicine: W. Taylor, First Prize (£3) and Medal; J. J. O'Donnell, Second Prize (£1) and Certificate. Theoretical Surgery: W. Taylor, First Prize (£3) and Medal; H. R. Sweeny, Second Prize (£1) and Certificate; A. M'Cann and J. J. O'Donnell, Certificates. Midwifery: W. J. Trewhella, First Prize (£3) and Medal; M. D'Exeter Jordan, Second Prize (£1) and Certificate. Physiology: W. L. Martin, First Prize (£3) and Medal; E. C. Hayes and A. M'Cann, Second Prize (10s. each) and Certificates. Chemistry: M. J. Carroll and E. W. Siberry (equal), First Prize (£2 each) and Medals. Mayne Scholarship, £15: G. Hamilton. Operative Surgery: G. Hamilton, First Prize, Gold Medal; O. W. Elsner and J. C. Prittie-Perry (equal) Second Prize, Silver Medals; H. G. LeFanu and F. Warren (equal) Certificates. Practical Chemistry: H. Eardley, First Prize (£3) and Medal; H. F. Conyngham, Second Prize (£1) and Certificate. Practical Histology: E. A. Meeke, First Prize (£3) and Medal; E. C. Hodgson, Second Prize (£1) and Certificate. Materia Medica: E. J. Moore, First Prize (£3) and Medal; E. A. Meeke, Second Prize (£1) and Certificate. Pharmacy: R. M. Hamilton, First Prize (£3) and Medal; H. B. S. Montgomery, Second Prize (£1) and Certificate. Medical Jurisprudence: J. J. O'Donnell, First Prize (£3) and Medal; L. F. Corbet, Second Prize (£1) and Certificate.

**TASMANIA.**—Dr. A. J. Neale, of New Norfolk, has been appointed a Justice of the Peace for the colony.

**WESTERN AUSTRALIA.**—Three new hospitals are being erected in the colony—namely, at Katanning, Newcastle and York.

**DEATH OF A CENTENARIAN.**—Hannah Cooke, who on Sept. 2nd last was said to have reached the age of 100 years, died on the 20th inst. at Kidderminster, of which town she was a native. She retained her physical powers and mental faculties until the day of her death.

**THE MUNTZ TRUST.**—The following are the grants made for the year 1892.—Queen's Hospital, £150; Children's Hospital, £150; Eye Hospital, £50; Homœopathic Hospital, £50; Ear and Throat Hospital, £50; Lying-in Charity, £50; Women's Hospital, £50; District Nursing Society, £50; Orthopedic Hospital, £25.

**THE MORLEY CONVALESCENT HOME.**—By the opening of the new wing of this institution it is estimated that from 1500 to 1600 patients can be annually accommodated. The foundation stone was laid about a year ago by the Lord Mayor. The cost of this extra accommodation at St. Margaret's Bay has amounted to £5000.

**THE SURGICAL AID SOCIETY, SUNDERLAND.**—The report of this Society, read at the first annual meeting which was held last week, stated that the local subscriptions for the year amounted to £54 17s. 3d. It was also announced that Mr. D. H. Haggie, J.P., had promised a life subscription of five guineas.

**PRESENTATIONS.**—A handsome travelling clock subscribed for by the poor of the borough of Chard has been presented to Mr. S. A. Clarke, with an address, for the kindly and valuable services he has rendered them in relieving their sufferings, and among whom, in consequence, he is a great favourite.—Dr. G. E. Morrison, resident surgeon of the Ballarat Hospital, Victoria, Australia, and Dr. E. G. Ochiltree of Ballarat have each been presented with an illuminated address by the Ballarat Branch of the Railway Employés' Association, in appreciation of professional services to several members of the Association.

**THE LIABILITY OF OWNERS OF INSANITARY HOUSES.**—At the Clerkenwell County Court on the 18th inst., before Judge Eddis and a jury, Emma Corfield, of 90, Atlantic-road, Brixton, was sued for damages for making certain misrepresentations respecting the sanitary condition of 91, Corbyn-street. The plaintiff had been consulted by the judge and had taken the case to the High Court, from which tribunal it was sent back to the county court. Evidence having been given that the house in question was in an insanitary state, the jury found for the plaintiff and costs. The amount claimed—£13 10s.—was for expenses of removal and doctor's bills.

**CHRIST'S HOSPITAL.**—It does not appear to be generally known that the Governors of Christ's Hospital are prepared to receive applications for the admission to Christ's Hospital of "children being sons and daughters respectively of persons distinguished in Literature, Science or Art, or in the service of the Crown, or for services rendered to the public or to Christ's Hospital." All such children must be between ten and eleven years of age, must pass the prescribed examinations, and must be subject to the provisions of the scheme for the hospital. A statement of the distinguished services of the parents must in every case accompany the application.

**CHESTERFIELD HOSPITAL.**—On the 20th inst., at the Stephenson Memorial Hall, Chesterfield, a meeting, presided over by his Grace the Duke of Devonshire, was held for the purpose of raising the necessary funds for adding a new wing to the Chesterfield and North Derbyshire Hospital and Dispensary. So great have the demands upon this institution been of late that additional accommodation has become absolutely necessary. Upwards of £1700 was raised at the meeting. Among the contributors were the following:—Duke of Devonshire, £500; the Duke of Rutland, £50; Mrs. Hunloke, £50; Mr. W. Arkwright, £50; Mr. C. Markham, £100; Colonel Seely, M.P., £100; Mr. W. G. Turbutt, £50; the Stavely Coal and Iron Company, £200; the Sheepbridge Coal and Iron Company, £100; and the Clay Cross Coal and Iron Company, £100.

**WESTMINSTER HOSPITAL MEDICAL SCHOOL.**—An Entrance Scholarship value £60 has been awarded to Mr. H. Hilton Cheesman.

**POST GRADUATE COURSE.**—Dr. Braxton Hicks having been prevented by his duties as examiner from giving his first lecture on October 25th will do so on November 1st and 22nd.

At the Medical Society of London on Monday evening next Dr. B. W. Richardson will read a paper on Intra-organic and Thoracic Auscultation—a preliminary chapter on a research in which he has recently been engaged.

The town of Sudbury, Suffolk, has been presented by Sir George Humphrey with a portrait of himself, and also of Mr. G. W. Andrewes, who was mayor of the town in the year of the Queen's accession, and likewise in the year of her Jubilee.

The annual general meeting of the St. George's Hospital Graphic Society will be held on Tuesday next, Nov. 1st, at 2.30 p.m. By permission of the board of governors the annual exhibition will be in the board-room of the hospital, and will be opened immediately after the meeting; it will remain open until the end of the week.

**FOOTBALL CASUALTIES.**—Of the following casualties, four occurred on Saturday. During the progress of a Berks and Bucks Junior Cup match, at Maidenhead, between the Maidenhead Norfolkiens and Maidenhead Reserves, a player collided with an opponent, sustaining a compound fracture of one of his arms. In a College match, at Oxford, a player fractured his leg. At the Wilts County Asylum, in a match between the Southbroom and the Asylum Teams, a player sustained a compound fracture of the right arm. Prior to the commencement of a match, whilst at practice, between Leicester A. and Moseley A. at Leicester a member of the local team fractured his clavicle. A reserve forward of the Darwen Club died on Sunday from injuries received in the abdomen whilst playing against Newton Heath in a combination match in the previous week.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher." We cannot undertake to return MSS. not used.*

### A PATHOLOGICAL BANQUET.

AT Rome a congratulatory symposium was given to Signor Adolfo Rossi, correspondent of the *Tribuna*, on his safe return from Hamburg, whither he had been sent to report on the outbreak of cholera. The menu was intended to give the guests—some fifty in number—a notion of the dangers Signor Rossi had encountered in the discharge of his commission. Here it is:—

"Recipe—Bacilli virgola al consommé—Pesci dell' Elba in salsa inquinata—Filetto alla 'Stanhope'—Cultore di fagiolini—Polli arrosto uso Koch—Gelato algido—Dessert, frutta e disinfezioni a piacere—Iniezioni epidermiche di Chianti—Cantanoclium di Champagne."

(*Nota*) Bacilli-virgule al consommé—Elbe fish with river sauce—Filet à la "Stanhope"—"Cultures" of *haricots verts*—Roast chickens à la Koch—Ice *frappé*—Dessert: fruits and disinfectionary ad libitum—Subcutaneous injections of "Chianti"—Champagne imbibed à la Cantani. "In spite of its alarming bill-of-fare, the banquet received ample justice," says the *Tribuna*, which journal seems to think such pleasantries a not ineffectual way of laughing down the tendency to panic which such epidemics evoke among Italians.

*M.R.C.S. (Bournemouth)* should apply at the offices of the company.

*Mr. Hugh Lane (Bath).*—The paper is receiving attention.

### "AN IRREGULAR TAX ON MEDICAL PRACTITIONERS."

To the Editors of THE LANCET.

Sirs—Medical men who complain that the coroners' officers expect the odd shilling of their fee should request the coroners of their districts to pay them by cheque, which is always the method of payment here. I am, Sirs, yours truly,

Plymouth, Oct. 10th, 1892.

J. ELLIOT SQUARE.

## ARE MEDICAL MEN BOUND TO GIVE DEATH CERTIFICATES?

*Mr. Laffan.*—Registered medical practitioners are certainly bound to give death certificates in cases which they have attended, as Mr. Laffan will see if he reads the 20th Section of the 37 and 38 Vict., cap. 83, passed in 1874, an extract from which is given in the death certificate book supplied gratuitously by the Registrar-General. By Section 30 penalties are imposed for not giving any certificate required by the Act, the penalty not to exceed forty shillings. Clause 3 of Section 20 provides that when an inquest is held a medical certificate need not be given.

*Dr. Forbes-Ross.*—Our correspondent is inconsistent surely in some of his statements. Thus whilst he denies the presence of potassium he admits the presence of albuminoids, which, he says, "must of necessity contain potassium salts." The phosphates were found in the preparation after incineration, as is distinctly stated. The test for potassium was not that which our correspondent mentions, but one upon which the formation of crystalline tartrate depends when tartaric acid is added to the solution. The fact that the preparation "digests" milk is no proof that it digests itself. We thank our correspondent for his letter, and are glad that he entirely agrees with our remarks respecting the fitness of the article for diabetic patients.

## "MIDWIVES' REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—If every member of the profession would place on record but one of the instances of flagrant ignorance on the part of midwives which are constantly coming under our notice a mass of evidence would soon be accumulated which would perchance cause those enthusiasts for "cheap doctoring" who are proposing to register these unskilled persons to pause. The following is a case in point.

Some time ago I was attending the worst case of erysipelas I ever saw either in hospital or private practice. A midwife who is reputed to do the most extensive practice of any woman in the town was a neighbour of my patient. At my second or third visit I found this midwife in the sick room. As soon as I heard who she was I told her that the case before her was of a very infectious nature, especially as regards puerperal patients, and that if any of her patients became infected by her the result would more than likely be fatal. This produced no effect. She was very pressing to be allowed to hold the patient's limb while I dressed it, and it was only my declaration that I would at once leave the house if she laid her hands on the bed that kept her off. Notwithstanding this, she came on several subsequent occasions into the room, even when I was there. That she would have been utterly incompetent to deal with, or even to recognise, any effects of septic infection which her patients might have exhibited was proved by a more recent experience. I was called in to see a patient whom she had attended in her confinement when the child was a week old. The patient had felt herself ill for some days, but the midwife declared that she was going on satisfactorily. When I saw her her temperature was 101° F. There was an obvious mass of exquisitely tender pelvic cellulitis reaching from the uterus to the brim of the true pelvis on one side, and the patient experienced almost agonising pain when fecal matters passed through the rectum, showing that the cellulitis extended far both deeply and backwards. The midwife was unable even to realise the necessity for obtaining more skilled assistance. If the order for decorating with diplomas the midwives in practice at the present time had gone forth this woman would certainly be as much entitled as anyone to be registered, and as—unfit.

I am, Sirs, yours faithfully,

A SURGEON.

Oct. 17th, 1892.

## PECULIAR SYMPTOMS OF POISONING BY SANTONIN.

To the Editors of THE LANCET.

SIRS,—The following case may be of interest to your readers (I have never seen or heard of a similar one). I found my oldest son, aged nine years, to be suffering from ascariides on the 9th of this month. In the evening I gave him an enema of quassia, which relieved the irritation until the 12th. As it returned I gave him, on the morning of the 13th, at 7.30, nearly five grains of santonin in milk. At 8.15 he had his breakfast of oatmeal porridge and would have gone to school, but I thought he would be better at home. About 9.15 I asked him to do something for me, to which he replied, "Yes, father." He did not do it, and after a minute I asked him if he did not hear me, to which he replied, "No." I noticed he looked pale, so went to him and carried him on to a couch. He was no sooner laid down than he turned a nasty bluish-green colour, the lips became blanched, limbs convulsed, teeth clenched, eyes wide open, pupils dilated, pulse absent at wrist, and he was bathed in a cold, clammy perspiration and unconscious. I forced open his teeth and gave him some brandy-and-water and went off at once for my nearest colleague. In about ten minutes the twitchings became less and the pulse began to return at the wrist. When my colleague came he was improving, but remained unconscious until 10.30, when he spoke a few words and then fell into a sleep. He was not himself for the rest of the day, but now seems quite well. If any of your readers have seen any such experience in similar cases I should be glad to hear of them. I must confess I thought my child was dying. I did not think the dose excessive.

I am, Sirs, yours truly,

Oct. 17th, 1892.

M.R.C.S.

## WINTER QUARTERS.

*R. J. S.* writes:—"Your leading article (Oct. 8th) on 'The Departure for Winter Quarters' will be read with much interest and profit. I beg leave to suggest, however, that those who have to winter abroad would find their requirements exactly suited during October, and even in the last week or two, at Pau. Pau has much to recommend it. It is undoubtedly the best-drained town in the south of France, and the cholera has never been known to visit it. Its large English-speaking colony makes it seem almost like home to the English. It has a pure and abundant water-supply. Its climate is, owing to its altitude (between 600 and 700 feet) peculiarly dry and at the same time soft, balmy and invigorating. It is on the road to the Riviera by the Midt Railroad via Toulouse. The weather for the last three weeks has been almost perfect—genial, warm and agreeable, with just enough rain and storm to give pleasant variety. If the weather is bad at Pau it is sure to be worse elsewhere in the north." We allow our correspondent's statements to speak for themselves, but we must point out that in several points he is in error. Pau does not possess a dry climate. The rainfall is forty-three inches, and rain falls on 119 days in the year (cf. Nice, with twenty-five inches of rain and sixty days on which rain falls). Nor can the climate of Pau be correctly described as "invigorating." In fact, authorities are pretty well agreed that it is remarkable rather for its sedative quality—a view with which our own personal experience entirely accords. Pau has rather receded in favour of late years; but its mild, soothing and rather moist climate suits some varieties of pulmonary and neurotic invalids very well, and we think our correspondent is probably right in maintaining that autumn and early winter are its best season. It is only by a considerable latitude of expression that Pau can be described as "on the road to the Riviera."

*Curio.*—Our correspondent should take the advice of a solicitor. It is impossible to give an opinion on a document which is not before us and the effect of which may be modified or governed by circumstances of which we are unaware.

## EFFICIENT VACCINATION.

To the Editors of THE LANCET.

SIRS,—One of the causes of the disrepute into which vaccination has fallen is, as one of your correspondents lately pointed out, the inefficient way in which it is frequently performed. I hold the office of public vaccinator for a small urban district, and on the occasion of my last series of visits to one of the out-stations only one baby was brought to be vaccinated, instead of the usual nine or ten. On my inquiring the reason the mother told me that Dr. — (naming an unqualified assistant) was vaccinating nearly all the babies at a small fee, and mothers would not bring their babies to have "four spots" at the station when they could have one, or at most two, small ones put on at home. No doubt the assistant takes the papers home to be signed, but how far the "one or two small spots" act as a protection is surely a matter of doubt.

I am, Sirs, yours faithfully,

October, 1892.

PUBLIC VACCINATOR.

A VERY OBJECTIONABLE COMBINATION OF MEDICAL ADVERTISING AND PHILANTHROPY AT TENTERDEN.

The following advertisement is from the *Kentish Express and Ashford News* of Oct. 8th. We need not say more of it than we have implied in the heading.

"FREDERICK FITZHERBERT JAY, M.D., late of Leamington, who has commenced practice at Tenterden as a general practitioner, will, upon receiving a recommendation from a lady or gentleman resident in Tenterden or the neighbourhood, give advice gratis to any poor person every Saturday, between the hours of three and five in the afternoon. Apply at private door (Mr. Freeman's), West-View House."

## STATUES OF EMINENT MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Your Paris Correspondent, in calling attention to the statues of Broca and Ricord, mentions Harvey's statue at Folkestone as the only statue to distinguished English medical men which he can remember. There is an excellent statue at the Fountains in Kensington-gardens of Jenner, which was, I believe, first erected in Trafalgar-square in front of the Royal College of Physicians, but afterwards removed to its present site in consequence of the agitation in Parliament against vaccination.

I am, Sirs, your obedient servant,

Oct. 22nd, 1892.

CHAS. ROBERTS.

## THE HISTORY OF QUACKS AND QUACKERY.

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly give me references to works or notices respecting quacks and their doings? I have promised to give a lecture on the subject, and shall feel thankful for any information that may prove of service in its preparation.—I am, Sirs, yours truly,

October, 1892.

NEWSPAPERS.—Surrey Advertiser, West Middlesex Standard, City Press, Weekly Free Press and Aberdeen Journal, Local Government Chronicle, Reading Mercury, Windsor and Eton Gazette, Hertfordshire Mercury, Our Dumb Animals (Boston, U.S.A.), Mining Journal, Leeds Mercury, Scotsman, Bristol Mercury, Liverpool Daily Post, Food, Drugs, and Drink Journal, Yorkshire Post, Windsor and Eton Express, Cleckheaton Guardian, Guy's Hospital Gazette, West Middlesex Advertiser, Elgin Courant, Law Journal, Lincolnshire Chronicle, Electrician, Midland Counties Express, Derbyshire Times, Dartmouth Chronicle, Canterbury Journal, Waterford Mirror, Worcestershire Chronicle, Birmingham Gazette, Sheffield Independent, Montreal Gazette, Whitehall Review, Court Circular, Sunday Times, Le Temps (Paris), Builder, Observer, European Mail, Dundee Courier, Woodford Times, Manchester Guardian, Architect, Bolton Evening News, Carnarvon Herald, Evening News and Post, Kidderminster Shuttle, &c., have been received.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year .....	£1 12 6	Six Months .....	£0 10 8
TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES ABROAD .....			
		One Year	1 14 8

\*. \* In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 8d., instead of £1 10s. 10d., as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

## Post-graduate Lecture

ON

THE GREAT PRACTICAL IMPORTANCE OF  
SEPARATING RHEUMATOID ARTHRITIS  
FROM GOUT.*Delivered at the Central London Sick Asylum, Oct. 13th, 1892,*By **SIR ALFRED B. GARROD, M.D., F.R.S.,**PHYSICIAN EXTRAORDINARY TO H.M. THE QUEEN; CONSULTING  
PHYSICIAN TO KING'S COLLEGE HOSPITAL.

GENTLEMEN,—Let us suppose that we are examining a diseased joint—say, a knee,—and we find it swollen and out of shape, perhaps showing evidence of containing fluid and possibly exhibiting some redness and heat of surface. These symptoms we can ascertain at once by touch and sight; but we are unable, unless we proceed further, to discover the real alterations which have taken place in the articulation or to know the condition of system which has given rise to the morbid state of the joint. 1. It may possibly have arisen from some accidental sprain which has excited traumatic inflammation of the joint. 2. A gouty condition of the system may be the cause. 3. It may be the result of true articular rheumatism. 4. Pyæmia due to the presence of pus in the blood may have caused the appearances we have noticed. 5. It may be the result of what may be termed "urethral rheumatism"—a disease in many respects allied to pyæmia, and connected with the formation and absorption of a specific form of pus. 6. It may arise in a condition of the system which may be termed "rheumatoid arthritis"—a condition which I shall have occasion to dwell upon in this lecture, and which therefore I need not speak further of at present. In order to have a chance of combating with success the various forms of articular disease, it is absolutely essential that we should have a clear insight into the various pathological changes which the different structures exhibit when carefully examined, and likewise a knowledge of the many morbid conditions of system in which they may occur.

Having but a single hour at my disposal I think I shall spend it more profitably in attempting to clear up one or two points of great practical importance rather than in treating of many in a less complete and satisfactory manner. That the points I have chosen are of the greatest importance may be gathered from the fact that hundreds, probably thousands, of patients have been reduced to a crippled state simply from want of rightly understanding them. The subject I shall select is the differential diagnosis of true gout, and an affection, formerly, and even now, by many medical men termed "rheumatic gout." The study of articular affections some thirty years ago led me to the conclusion that the majority of the cases then called "rheumatic gout" were related neither to true gout nor true rheumatism, and that they had an independent pathology of their own; and if such is the case, the term "rheumatic gout" was doubly wrong. I must confess that even before I proposed to change the name of the disease it struck me as very peculiar that there should be such a compound malady; it would have appeared to me no more surprising to hear of scarlet-fever-measles or any other combination of diseases. I proposed the name of "rheumatoid arthritis"—a name which does not imply any error, but assumes the disease to be an arthritic or joint disease having some of the external characters of rheumatism,—and the name has of late years been very extensively used, nor should I wish to alter it, although I allow that a better name may one day possibly be found. Arthritis deformans has been applied to the malady, and this again is not an erroneous name, though in the earlier stages of the disease it is by no means a characteristic one. The term "rheumatoid arthritis" is nearly, or at least half, as bad as that of "rheumatic gout," as it implies the existence of one error instead of two. I am not aware of any two joint affections which are so frequently mistaken for each other as gout and rheumatoid arthritis, and I know of no errors of diagnosis which have led to so much mischief; nor is it difficult to understand why such terrible results are apt to follow, seeing that both the medicinal and dietetic treatment so useful in the one disease may prove most injurious in the

No. 3610.

other. My case books, even of the last ten years, contain fearful instances of the ill effects which may arise from such errors of diagnosis; and if in the present lecture I am able to prove to you the truth of these statements, I shall feel that I have not devoted my allotted hour to a useless purpose.

Before selecting actual cases of these diseases and pointing out the way in which one may be separated from the other, it will be necessary for me to bring before your notice the principal features which characterise both gout and rheumatoid arthritis. This I shall endeavour to do in as few words as possible; and first we shall speak of gout. You have probably been accustomed to hear gout spoken of as simply a joint affection, in which occasionally the disease is transferred either from one joint to another, or sometimes from a joint to some other organ. This was my own idea a few years ago; but a very extensive experience has disposed me to look upon gout as a systemic disease, invariably connected with a peculiar and characteristic state of the blood, which I shall shortly describe, and to consider that it may and does frequently exist for many years without the development of any joint affection, but confining itself to the production of changes in numerous other tissues and organs. The characteristic features of gout may be thus described:—1. In all cases of gout, articular or not there is an excess of uric acid in the blood. 2. The tissues of the joints which have been subjected to gouty inflammation always exhibit deposits of uric acid in the form of the biurate of sodium in a crystallised state, and this deposit must be looked upon as the cause, not the result, of the inflammation—in other words, the deposited urate is antecedent to the inflammatory action. 3. The inflammation which occurs around the deposited urates produces a destructive action upon them. 4. Gout is often manifested in non-articular structures, as the skin, kidneys, bladder and prostate, throat, digestive organs, muscles and so forth. 5. (a) Gout has a close relation to the patient's diet, especially to his alcoholic beverages; (b) gout is much more common in men than in women; (c) gout is a strongly hereditary disease. We must now discuss at least some of these different statements.

1. Many years have now elapsed since uric acid was discovered in the blood. In June, 1847, I procured the blood of a patient suffering from a severe attack of typical gout, and on carefully examining the same was enabled to separate uric acid from it, either in the form of the crystallised acid or as the biurate of sodium. These researches were published in the Transactions of the Medical and Chirurgical Society in 1848 and following years. It may perhaps be well to mention that at the time I made these observations there was no difficulty in procuring a sufficiency of blood; venesection was constantly performed and even looked for by patients who had any inflammatory disease. At the present time it would be practically impossible to make such investigations as I then was enabled to pursue.

2. A proof of the truth of our second statement—namely, that the deposition of urates in the tissues is antecedent to the occurrence of the inflammatory action—is seen during the formation of the little bodies which so often occur in gouty subjects in the helix and other parts of the external organs. At first we observe a little vesicle; the contained fluid is almost transparent; this fluid gradually becomes more or less opaque or milky, then creamy; afterwards the consistence gets cheesy, and lastly chalk-like in its hardness. In by far the great majority of cases these deposits in the ear are unattended with any inflammation; there are, however, well-marked exceptions to the rule. Every post-mortem examination shows the uniform occurrence of urate deposits whenever any joint has been attacked with gouty inflammation, and I was enabled to show the deposits in two interesting cases: one that of a man who during life had two distinct attacks of gout confined to the ball of one great toe, and in this subject examination showed the deposit in this joint only; the second case was also that of a man who had but one attack thirteen years before his death, and in this instance the deposit was found in parts known to have been implicated during life, and in these only. Extensive deposits of urates are often found in the bursæ or the elbows, which at times are unaccompanied with inflammation.

3. If a large joint, such as a knee, which has been often subjected to gout be examined after death, it will be seen that the deposits on the synovial surface do not approach near to the bloodvessels, which would seem to show that the bloodvessels of the inflamed surface have caused the partial

T

destruction of the previously deposited urates. That the blood of any tissue in a state of gouty inflammation contains less uric acid than that of any other part of the same subject is not difficult of proof and may be easily shown by the application of a blister to the part. I have found, for example, that the fluid from the inflamed dorsum of the hand has been free from uric acid when that from the chest of the same person was rich in that acid. The slight inflammation caused by the blister itself to some small extent destroyed the uric acid.

4. In the non-articular manifestations of gout, which are far more numerous and frequent than I was formerly disposed to admit, and which are perhaps less frequently found in hospital practice, the parts most commonly affected are the following:—

(a) *The Skin.*—Now and then, in gouty conditions, we find different varieties of erythema. It may, however, be questioned if this cutaneous affection is more frequent in gout than in many other diseases—it is certainly much less common than in rheumatism. Eczema, on the other hand, is the skin disease which is so characteristic in gouty subjects; it presumably occurs before the articular manifestations and becomes relieved by their occurrence; but it often remains during the course of the joint disease, and at times continues for an almost indefinite period afterwards. It is not uncommon to meet with eczema in the children of gouty parents, even when they are still quite young. On the other hand, it is often the bane of gouty subjects in the latter years of their lives. The production of eczema is doubtless a means of getting rid of uric acid from the blood; but, contrary to what might have been at first supposed, the fluid of eczema contains no urates. This is easily explained, for each vesicle, the product of inflammation, causes the destruction of the acid, which is converted into other products. I have as yet failed to discover uric acid either in the liquid exudation of acute eczema or the scales from the surface of the dry variety.

(b) *The kidneys.*—The kidneys are perhaps equally as liable to be attacked, but certainly not so early in the disease, as the skin. Traces of albumen are most common in the urine of gouty patients, often most minute in quantity, but still indicating the presence of some gouty action, and of a deposit of urates in the intertubular structures. In the early stages I frequently found albumen to be quite absent during the complete intervals of gouty attacks. With regard to the occurrence of gravel and calculus, it may be remarked that some gouty subjects are troubled with calculi, and the children of such are rather liable to this malady. My friend, Sir William Roberts, has well said in his recent Croonian Lectures that “many gouty people are never troubled with gravel, and conversely that many subjects of gravel are never troubled with gout. In both complaints there is an aberration of uric acid; but the error is essentially different in the two cases, both in regard to its site and to its nature.” Albumen in the urine is doubtless often caused by a gouty change in the kidney; but, on the other hand, albuminuria from any cause will certainly predispose to the production of a gouty state of the system.

(c) *Muscular system.*—The voluntary muscles are often affected in gout in the form of cramps, and this symptom can sometimes be made use of as a diagnostic mark. Nothing is more common than to find patients complaining of cramp in the calf of the legs, and feet early in the morning for days and weeks before the commencement of an attack of joint affection, which passes off at once when the articular inflammation comes on. My experience would lead me to think that the involuntary muscles are not very frequently affected in gout. The heart is supposed to be so at times, but true spasm in an otherwise healthy heart it has not been my lot to become acquainted with. Lumbago and other forms of the so-called muscular rheumatism are very frequently associated with a gouty state of the system.

(d) *Digestive organs.*—For weeks, months and even years, before an attack of gout in the joints it is not unfrequent to find patients suffering much from indigestion, usually of an irritative character, often accompanied with much flatulence, pain, red tongue and hæmorrhoids—symptoms indicating that the mucous membrane of the stomach is slightly inflamed, and that the portal vessels are in a state of congestion. I have also thought that gouty patients are very liable to have a loaded state of the colon and fulness of the liver; but whether this condition is more common in gouty than in other subjects I could not positively say. When gout has been induced by the mode of living it is probable that the whole portal system has been also disturbed by the same

cause. The throat, nose, prostate gland and testicles are at times implicated in gouty patients. Sore-throat is exceedingly common and often alternates with other manifestations of the disease. The tonsils usually exhibit a peculiar purplish colour, without showing any appearance of acute soreness. In a very few cases I have seen the end of the nose unmistakably affected by gout, causing great inconvenience and suffering. The prostate gland is not unfrequently attacked, and its gouty character can be easily seen after a time by the quick subsidence of the symptoms, especially if a large joint becomes inflamed. In several cases I have seen one or both testicles attacked with gouty inflammation.

(e) *Circulatory and respiratory systems.*—There is a very prevalent idea in the profession, as well as amongst the public, that the heart is often attacked by gout, and there are records of many men, some of considerable eminence, who have died suddenly from this cause. I have never myself seen acute pericarditis or endocarditis brought on during an attack of articular gout. Doubtless the subjects of gout very frequently have chronic valvular disease, as the causes which induce gout lead also not uncommonly to slow valvular changes.

#### RHEUMATOID ARTHRITIS.—ARTHRITIS DEFORMANS.

It will now be necessary for me to state the chief characteristics of the second disease, which we have agreed to call “rheumatoid arthritis,” before we attempt to separate the two maladies from each other, or bring under your notice illustrative cases of these maladies. 1. In rheumatoid arthritis there is an absence of any excess of uric acid in the blood; in this respect it differs altogether from gout. 2. The examination of the joints which have been implicated in rheumatoid arthritis fails to exhibit any evidence of the presence of biurate of sodium, either on the surface of the cartilages or in the surrounding articular tissues. 3. On the other hand, even in the earlier stages of rheumatoid arthritis, there is a marked alteration in the cartilages; there is ulceration from the very first, and in time the bones become completely denuded. In one instance a man under my care in the hospital had the inter-articular fibro-cartilage of the left maxillary joint completely removed, the surface of the maxillary bones denuded and the projection of bony prominences fitted so closely as to cause complete locking of the jaw. 4. Rheumatoid arthritis, as far as my knowledge of the disease at present goes, manifests itself only in the joints. We have no evidence of the existence of any morbid state of the blood. There is in all cases some defect of nutrition which appears to affect such tissues as the cartilages, which are comparatively free from vascularity. In this respect it differs completely from gout, where so many organs of the body may be implicated. 5. There certainly is a close connexion between rheumatoid arthritis and the state of the nervous system. Severe and long-continued mental depression is a very fruitful cause of the disease; but physical causes, such as frequent losses of blood, will also lead to its development. 6. There is no known relation between the condition of the kidneys, skin or digestive organs and rheumatoid arthritis. 7. The selection of the joints which become implicated in rheumatoid arthritis differs much from what is seen to be the case in gout. A knowledge of this fact is often of much use in arriving at a diagnosis. If a first attack begins in the great toe specially it is highly probable that the case is one of true gout; the frequency of its occurrence in this locality is so great as to render the symptom almost pathognomonic. There are, however, a few exceptions which must be carefully investigated when they occur. There is a special tendency in rheumatoid arthritis to an affection of the jaw and also the back of the neck; the number of cases in which one or both of these parts are attacked is very great. I should imagine at least two-thirds of the patients affected with this disease experience these symptoms during its course. At times, however, the neck may become quite set from an ankylosis of some of the cervical vertebrae, and occasionally the jaw becomes so rigid as to require the removal of a tooth in order that nourishment may be introduced into the mouth. There is scarcely any other disease in which these symptoms are found; so that their occurrence is of great value in the diagnosis of this malady. 8. The effect of diet in rheumatoid arthritis is much less marked than in gout. I am not aware of any special articles of diet influencing the progress of rheumatoid arthritis when it is present, or leading to its first development. It may be regarded as certain that any diet which is insufficient to keep up

the general health leads to the increase of the disease; and, on the other hand, any diet which improves the strength tends to lessen the affection. With regard to alcoholic beverages, I may remark that malt liquors, port, sherry, champagne and other wines, so potent in the production and keeping up of true gout, have no influence in causing rheumatoid arthritis. This I shall be able to prove to you before the end of the lecture. Total abstainers are quite as liable to rheumatoid arthritis as those who have taken ordinary alcoholic drinks. I have had many cases illustrating this point—one a clergyman who had never in his life tasted alcohol, and whose father and mother had been rigid abstainers. 9. Females are more liable to rheumatoid arthritis than males, and there can be no doubt that the influence of heredity is very much less marked in rheumatoid arthritis than in gout. 10. Rheumatoid arthritis may occur at any age. I have seen a well-marked case in a child of three years and a half old; I have also seen it commence in patients eighty-seven years old; but the more common time is from about fifteen to thirty years. Gout, on the other hand, is much more commonly met with after forty years of age.

Having brought before your notice the chief characteristics of the two maladies which engage our attention in this lecture, I shall endeavour to point out such diagnostic marks of each disease as will enable us, with something like certainty, to separate the one from the other. I must here repeat that I consider it a matter of extreme importance to form a correct diagnosis, and that the failing to do so must not be looked upon as a mere pathological error, of consequence only from a scientific point of view. To mistake true gout for rheumatoid arthritis is, perhaps, of comparatively little importance; it might, and probably would, by the treatment adopted, lead to a prolongation of the attack and inconvenience to the patient; but to mistake rheumatoid arthritis for true gout is often the cause of irreparable mischief, and may lead to the worst form of crippling. Yet I feel absolutely certain that this is daily done with the most disastrous results. It is only this day on which I am writing these lines that I have met with two new cases thus mistaken. A few years ago I was written to by a physician of very high repute, a gentleman who had been for many years connected with one of our largest hospitals. The substance of his remarks was as follows: That he had been extremely interested in reading what I had made out concerning the two diseases we have been considering, but he practically allowed that up to that time he had in his practice failed to recognise the distinction, and had acted accordingly. It must therefore be admitted that physicians, who in most respects are fully up to their profession, may be in grave error in reference to the separation of gout and rheumatoid arthritis. This was certainly the case but a comparatively few years ago. In the moderately advanced stages of true gout, when chalk stones are visible either on the helix of the ears or bursa of the elbow or other parts, it is difficult to see how any error of diagnosis can be made, for urates are never deposited except in true gout. I must direct your attention to the fact that deposits often occur in the external ear before they are visible in other parts of the body, and this may become very important in diagnosis. In many cases I have been materially assisted by attending to this pathognomonic sign.

In the early stages of gout the diagnosis is, as a rule, very easy: the suddenness of its invasion, often during the night; the acuteness of the pain; the joint most frequently affected; the short duration of the attack, usually not more than ten days; the history of the case as to diet, and more especially as to the character of the alcoholic beverage; the presence or absence of hereditary predisposition—these taken together are usually sufficient to ensure a correct diagnosis. There are, however, cases of true gout occurring in elderly people, more especially in women—they often affect the knee or other large joint—in whom the inflammation is by no means acute, but the joint remains a long time affected. These cases are difficult to diagnose correctly. The effect of treatment in such cases assists greatly in the diagnosis. The fear, however, is usually not that true gout may be mistaken for rheumatoid arthritis, but that cases of this latter disease may be looked upon as of a gouty character. This error is infinitely more common and infinitely more serious than the other. Let us take as an example the case of a young woman who is suffering from inflammation of the ankle, wrist or hand, with little, or at any rate no great, constitutional disturbance. From my experience cases of this kind are constantly looked upon by many practitioners as of a true

gouty nature, and are treated accordingly. Moderate attention to the character of true gout and of rheumatoid arthritis would enable anyone to form a correct diagnosis. In such a case we should in all probability fail to find evidence of any hereditary predisposition or of any habit of the patient likely to lead to gout—for instance, the absence of eczema, cramps, kidney mischief and other gouty symptoms. We have, in fact, an alteration in one or more joints which, as far as we can make out at present, constitutes the disease. The treatment is usually of the following character: abstinence from meat (red meat especially), sugar and all alcoholic beverages. Many patients are not allowed vegetables, and fruits are often altogether prohibited. As far as medicinal treatment is concerned, salines, iodide of potassium and colchicum are most frequently administered. Under this treatment, accompanied as it frequently is by long immersion in baths, the invalid almost invariably gets worse, new joints become affected, and not infrequently the patient becomes gradually crippled.

I will first bring before your notice a few cases of rheumatoid arthritis illustrating most of the statements I have made about this disease, some of them showing the fearful effects produced by wrong treatment; others the marked good obtained by appropriate medicine and food. The following case is most instructive:—

CASE 1.—A girl nearly nineteen years of age came to me in October, 1891, in the following condition and with the annexed history. She had no hereditary predisposition to gout, and had up to seventeen years of age been in good health, but then she became weak, tired on exertion, and generally out of health. After about three months some swelling of the feet and ankles came on. She was then sent to a mineral water institution, where she remained three months under treatment. During this time the left elbow and hands became implicated, and soon after her return home one knee. When I saw her she looked somewhat emaciated and pale; the pulse was 84, small and weak. Besides the mineral water treatment she had been kept decidedly low; no meat nor stimulants being allowed. The left elbow was much injured, could neither be fully extended nor flexed; the right knee was limited in its movements, but less injured than the elbow. I prescribed for this patient the syrup of iodide of iron, to be taken twice a day, and two sulphur lozenges at bedtime, with two teaspoonfuls of cod-liver oil. As to diet, I ordered her to have daily a good amount of meat together with bread and vegetables, and with her solid food she was to take a moderate quantity of good stout. Between nine and ten months afterwards I again saw this patient, and her condition had wonderfully improved; all the functions were healthily performed and she had gained health in every respect. I suggested that she should persevere with the treatment, with the addition of five minims of the solution of arseniate of soda to the iodide of iron; the diet was to remain the same, and to include the cod-liver oil.

Now I think we may learn something from this case. I cannot say if it was called a gouty case, but certainly the treatment was most injudicious. Under the influence of the bathing, the absence of meat and stimulants, the disease made rapid progress, and joints previously free became implicated, and some, I fear, permanently injured; even shortly after her return home there was still a tendency to further mischief. Anyone examining this case, unless lamentably ignorant, must have felt assured that it could not have been of a true gouty nature. The absence of hereditary tendency to gout, the age and sex of the patient, are alone sufficient to negative the idea of true gout, even in the early stages, and the subsequent injury to the joints at once pointed out its true nature. This case is also instructive as showing the effect of diet and medical treatment. The lowering effect of the treatment produced by the baths and the poor diet was well seen, and, on the other hand, the rapid and marked influence of the tonic treatment and the meat diet and stout were equally apparent. Quite recently (three months after having last seen the patient) I have heard of a still further improvement in all respects from her father, a medical man, who fully recognises the error which was made in his daughter's case, but who had naturally entrusted her treatment to other hands than his own. Had this young lady been put under her present treatment a year before she would in all probability have been spared her injured elbow and knee, which at the best can only be alleviated, as some ulceration of cartilages has doubtless taken place.

I may remark that this patient had the characteristic jaw and neck affection well marked.

The following is another instructive case.

CASE 2.—Mrs. —, aged thirty-three, married, no children. Seen March, 1889. Has had slight pain in different limbs for five or six years; but about four months ago the hands became swollen and cannot now be fully closed; they are also somewhat painful. The elbows are slightly implicated, as also the wrists. There is the characteristic affection of the neck and jaw; the right knee is a little swollen and stiffish; all the pains are worse while the patient is in bed. For some years there have been hæmorrhoids, which have bled much at different times. The pulse is small and quick, and there is some anæmia. This was a well-marked, but not very advanced, case of rheumatoid arthritis. The patient was put under a treatment I frequently adopt, and the progress of the case was as follows: In July the right knee had become straighter and the general health had improved; there had been an operation for hæmorrhoids in May, which had stopped the loss of blood and thus taken away any constant source of debility. In October much improvement had taken place, although she still suffered from her knee and ankle; no new joint had been attacked since she began this treatment. In April, 1890, she was fairly well. In December, 1891, she was remaining well, but had not taken much medicine, except that she had continued regularly the sulphur lozenges. In May, 1892, the patient still remained well; also in July.

This case is a good example of the value of a tonic treatment in rheumatoid arthritis. I feel absolutely sure that had the true nature of the disease under which she suffered been mistaken and had she been treated in a way supposed to be desirable in gouty conditions of the system, she would long ere this have become a cripple. The treatment adopted consisted mainly of syrup of iodide of iron and small doses of arseniate of soda, sulphur daily in small doses, cod-liver oil, a generous meat diet and claret with the meals.

CASE 3.—A man aged fifty-five, after having had bronchitis for some months, which had lowered his system and caused him to relinquish his occupation, noticed that his hands were becoming stiff; the small joints were large, tender and painful, the wrists stiff, the elbows limited in movement and incapable of either full extension or flexion; there were also well-marked stiffening and pain at the back of the neck, and especially of the right maxillary articulation. The hips were affected so as to prevent him from crossing one thigh over the other, and the knees were somewhat stiffened. This was a case not unlikely to be taken for one of gout. The age and sex of the patient were somewhat in favour of that idea; but the gradual coming on of the disease and the mischief done to the joints were, on the other hand, much against it. He was sent to a well-known mineral water establishment and went through the course, but to his surprise had not found any relief. On the contrary, he was rather worse for the treatment, and the disease was slowly but very steadily on the increase. The injurious effect of this treatment was in favour of its being rheumatoid arthritis. In such a case all lowering treatment is sure to be followed by an aggravation of the disease, and the only chance of arresting it is the steady perseverance in a proper tonic medicinal treatment and diet, and, in fact, everything should be done to sustain the general health at the highest possible pitch. Colchicum and all such drugs should be avoided.

The following is an instructive but terrible case:—

CASE 4.—A young lady aged twenty-four. This patient when she came under my notice was in the following state: Nearly every joint in the body was ankylosed; her neck was quite fixed; she was unable to turn her head in the least degree from side to side; her lower jaw was quite set fast, and she could only be fed from the absence of one or two teeth allowing a tube to be introduced for the purpose of giving nourishment; the elbows were perfectly fixed at about right angles, the wrists were rigid and the fingers curved inwards and unable to be either further flexed or extended; the knees were fixed at a right angle and the ankles and feet more or less useless. I cannot call to mind ever having met with a more complete cripple; she could not attempt to stand, and she was obliged to be propped up with pillows when she was placed in an armchair. The history of this case was most lamentable. She had been suffering from well-marked rheumatoid arthritis for some months, but still was able to walk about. She was persuaded, or her friends advised her, to try the effect of Turkish baths. She went to a hydropathic institution, where she remained thirteen weeks, and during that time had always one Turkish bath, often two, a day; it was during this lowering treatment that joint after joint became ankylosed,

and she was reduced to the state of utter helplessness which I have described. I must add here that it has been my lot to have seen many cases of rheumatoid arthritis which have been very seriously made worse by the use of these baths. I do not consider that they act injuriously by their effect on the skin, but by their causing great debility and prostration of the system. This is a point to be thought of carefully when an idea of ordering baths in this disease is entertained.

CASE 5.—A gentleman aged forty-nine was seen in July, 1869. He had no marked hereditary predisposition to any disease. For about nine months the left shoulder had been troublesome, and from that time the disease gradually progressed; the right shoulder, back of neck, jaw, elbow, wrists and hands, knees, ankles and feet were one after the other affected; in some of the joints the movements were limited, as the elbows, which could not be fully flexed, extended or rotated; the patient had become thinner and somewhat pale. He was put upon a tonic treatment and took iodide of iron with much benefit, also a nutritious diet. He persevered in this treatment for some years, going to Aix-les-Bains two or three times and once to Schwalbach. He steadily improved, although I must confess at first I much feared he would become crippled. I saw him in September, 1888, nineteen years after his original visit, and he was then quite well. No case could possibly have been more satisfactory than this one. From the first he had the characteristic symptoms of the jaw and neck stiffening and was altogether in a very unsatisfactory condition. His complete recovery and his remaining well for so many years must be attributed entirely to the medicinal, dietetic and hygienic treatment which was employed.

I could bring forward many very similar cases, but in most the time since recovery is of less duration. Although I have said that cases of gout and rheumatoid arthritis can generally be separated from each other without much difficulty by attention to the various characteristic symptoms of each disease, still I have no hesitation in stating that instances now and then come under our notice in which there is much obscurity, which may require a knowledge of the effect of treatment before we can feel a certainty of a correct diagnosis. I will bring before you a case of this kind.

CASE 6.—A lady aged twenty-three. She knows nothing of the health of either parents or grandparents. About nine or ten months before I saw her she had swelling, heat and pain, first of one, then of the other foot, which lasted from six to eight weeks in all; and the inflammation was confined to the ball of the great toe. She afterwards remained free from any symptoms till a month before I saw her, when the same thing occurred as at first, but this had almost subsided and there was a little tenderness only remaining. The patient was very weak, distinctly anæmic, and somewhat breathless on exertion, and a blood murmur was heard in the neck. She had suffered from eczema of the ears, face, hands and legs when ten years of age, but not of late. Catamenia deficient, pale, and not occurring more than once in two months or so. Heart sounds healthy; no marked indigestion. She had been almost an abstainer from alcohol, and had taken but little meat. Pulse small, 96. In the interval between the first and second attack the toe-joints became well, except that there was a little enlargement. What was the nature of this case? Many things would point against its gouty character, as age, sex and mode of living; but there were two well-marked symptoms which could not be passed over. The most important was the locality of the inflammation—the ball of the great toe in each foot. Now we have seen that this is the joint which is *par excellence* affected in true gout; but I have known cases of severe gout of long standing in which the great toes have never been attacked; and, on the other hand, I have seen these joints affected in rheumatoid arthritis, though perhaps never so exclusively as in the case under consideration. The previous existence of eczema was somewhat in favour of the gouty nature of the disease; but as this occurred when she was young it might not have had any relation to a gouty state of the system. The great-toe joint remaining somewhat large in the intervals between the attacks was in favour of the affection being rheumatoid arthritis, as true gout seldom leaves appreciable enlargement from a first attack. I should be inclined to think, upon the whole, that the case was one of rheumatoid arthritis. Had I seen the effect of treatment I should soon have been quite certain as to the correctness or not of the diagnosis. After a little time I may probably have an opportunity of coming to a more definite diagnosis.

CASE 7.—A lady aged fifty-nine years; she knows nothing about her hereditary predisposition, as her father died when

she was one year old, her mother when she was two years of age. She herself has had nine children, their ages varying from thirty-eight to twenty-six. For nearly five months she has suffered first from the right knee, which became swollen and painful, tender, and contained some fluid. All the functions were performed well; pulse 84, good. Such a case as this is not uncommon and the correct diagnosis is important, not only to the patient, but to the medical man, as far as his credit is concerned. It certainly was a slight case either of true gout or of rheumatoid arthritis. In favour of its being of the nature of the latter disease there were but few symptoms; the general health was fairly good; no depressing causes had been at work. The only thing in favour of it was the duration of the disease, nearly five months. Still, from the appearance of the knee-joint I could not have said which diseased condition of the system was the cause of the articular affection. A further investigation of the case will, however, enable us to come to a right conclusion. It was noted that there had been two patches of eczema, one on the left shoulder, which had disappeared; the other, a large one, on the right thigh. This rendered it very probable that the disease was gouty. Again, before the knee became inflamed she had been much troubled with cramp in the calf of the legs and also a numbness of the hands and arms on waking in the morning; both these are markedly gouty signs. As to her habits, she had usually drank sherry, and often, when nursing her children, stout. These beverages were likely to induce a gouty habit, and, taking all these circumstances into consideration, I looked upon the case as one of gout and prescribed accordingly. The treatment consisted in the administration of ammoniated tincture of guaiacum, citrate of lithia and a very small quantity of colchicum, under which the knee rapidly became better. The effusion in a fortnight could not be detected, and in a short time the patient was well, the pulse sinking from 84 to 72, and she was quite able to walk. In this case the effect of treatment became quite a diagnostic mark. Had I prescribed for her as I should have done if I had entertained the idea that the case was one of rheumatoid arthritis, I feel quite sure the disease would have increased rather than diminished, and that she would have long remained in the condition in which I first found her. Time does not allow me to speak of many cases of gout, nor do I think it is necessary to do so, as the difficulty of making a correct diagnosis in such cases is usually small, and, as I have already said, any error would be of less practical importance.

Before finishing I think I must say a few words about a term which has been made use of lately—"rheumatic arthritis." I have already said that I consider this term erroneous if applied to the disease rheumatoid arthritis, as it would imply that it had in it an element of true rheumatism, which I altogether deny, but Dr. Lane has recently tried to differentiate between true rheumatoid arthritis and what he terms "rheumatic arthritis," considering that a disease exists which is connected with rheumatism but still is not simple rheumatism. I quite think that the occurrence of true rheumatism, in the form of rheumatic fever, may be one of the many causes which lead to the production of rheumatoid arthritis; but if the induced disease has the characteristics of rheumatoid arthritis I do not think this name is appropriate. The disease may be the same whatever the causes which may have given rise to it.

In concluding this lecture I feel I must apologise for the imperfect manner in which I have treated the subject; but the shortness of the allotted time must be partly my excuse, and my own shortcomings I must not forget. I trust, however, I have been so far successful as to convince you of the intense importance of clearly diagnosing rheumatoid arthritis from true gout, and of making you realise that the health of your patients is greatly at stake and dependent on the correct knowledge and treatment of their cases. Want of time has been the only cause of my not bringing before your notice many other cases. My note-books are so full of them that their very number causes difficulty in their selection.

**SUDDEN DEATH OF A MEDICAL MAN.**—On the 21st ult., at the Holborn Town Hall, an inquest was held on the body of Mr. J. R. Gibson, F.R.C.S., who had been surgeon at Newgate Prison for fifty years, but was now retired. The deceased gentleman was found lying on the footway in Devonshire-street, Queen-square, on Oct. 20th. The medical evidence went to show that death was due to heart failure, and the jury returned a verdict of "Death from natural causes."

## INTRA-THORACIC AUSCULTATION: A NEW DEPARTURE IN PHYSICAL DIAGNOSIS.

*A paper read before the Medical Society of London on Oct. 31st, 1892,*

By BENJAMIN WARD RICHARDSON,  
M.D., F.R.C.P., F.R.S.

MR. PRESIDENT AND GENTLEMEN,—I had promised to bring before the members of the Medical Society of London this session a paper on Some New Researches in Synthetic Pathology, but as I was not prepared for so early a call for the paper as that which has been assigned to me I have been unable to complete it in the form in which I would wish to present it. It happens, however, that I have at hand a short communication which I have much pleasure in submitting to you, and which, because it is extremely simple and practical, will, I trust, be accepted as a substitute for the longer and more ambitious essay. I call the present essay a study of Intra-thoracic Auscultation: a New Departure in Physical Diagnosis, and I cannot introduce it to your notice better than by relating how it came into my mind and practice. A few months ago a patient consulted me who was suffering from serious and obscure symptoms referable, by the process of exclusion in diagnosis, to the upper portion of the alimentary canal. He had lost flesh to an extreme degree, was very feeble, had often a difficulty in swallowing food, at times retained food of a fluid or semi-fluid kind in the stomach for long periods, and then after suffering severe pain vomited it with difficulty, returning it in a partially digested state. I looked upon the symptoms with suspicion as possibly indicating malignant disease of the lower part of the œsophagus; but as I found he had been following an imprudent dietary I was content at the moment to regulate diet carefully and to prescribe a mixture of dilute hydrochloric acid and pepsine. He left me, to return in two months reporting himself in every respect better. He had gained in flesh, he retained food, was free from acute pain, had improved in strength and had lost the sense of weariness of mind as well as body, which had been most oppressive. He had determined to take a holiday, and I agreed with him that the change he suggested would be advantageous. I did not see this patient again for three months, when he consulted me once more in consequence of a sudden return of his worst symptoms, to which were added others pointing more decisively to œsophageal mischief low down in the tube. With difficulty he had partaken of a rather too copious meal one day previously, and soon afterwards had been seized with acute pain, which lasted until the undigested mass had been vomited with free secretion of the gum-like mucus characteristic of stricture. He was again greatly emaciated, presented a condition of circulation so feeble that I could scarcely detect the radial pulse, and the heart was so weak that it was difficult to distinguish clearly the two sounds.

I tried in this case what I have called the water-gurgle test for the diagnosis of stricture, as described in *The Aselepiad*, vol. vii., p. 332—that is to say, I got the patient to attempt to swallow fluid whilst I auscultated in the line of the œsophagus anteriorly and posteriorly. Whenever there is true stricture of the organic class I have usually found by this method a point where there is heard a loud gurgling sound on attempts to swallow, followed by a sharp noise as of a passing current of fluid through a constricted passage, and I do think there are few more characteristic points of diagnosis of stricture existing in the lower third of the tube. There was no response to this test in the present instance, and the patient expressed to me that the tumbler of milk-and-water which he had swallowed went down without his being conscious this time of obstruction. I turned, therefore, naturally to the use of the œsophageal tube—an operation which led me to the new facts I have to record. I passed along the œsophagus a medium-sized tube and ran it without difficulty down to the stomach. There was no serious obstruction at any part, but I thought I experienced some sense of friction of a very slight kind. Whilst endeavouring to be certain on this matter an idea which I had once before had in my mind, but had not before acted upon, suddenly occurred to me. Why not auscultate

through the exploring tube? At once I sliced off a portion of the free end of the tube obliquely, slipped over this sliced end the terminal part of the double stethoscope, and made in this fashion the exploring tube a continuous stethoscope. The effect of auscultating in this way was most interesting and satisfactory. I could hear soft friction of the tube against the walls of the œsophagus and was made quite sure that the friction was uniform throughout and that there was no special constriction or induration in any portion of the tube. When I passed the tube into the cavity of the stomach itself I obtained a sound new to me, like a gentle seething as of air or gas agitated in a thickish fluid and at times a gurgling sound of gas with another sound probably due to muscular contraction of the stomach itself. As the patient experienced no trouble or inconvenience during examination I had ample time for inquiry, and I leisurely withdrew the tube, noting the sounds audible in the course of the movement. In the tube at this time there were only two openings and those at the extreme end. I succeeded therefore in catching sounds at such points only as were in apposition to the openings. I withdrew the tube until the opening on the left side came in contact with that portion of the œsophagus that lies in immediate proximity with the heart. By previous auscultation of the heart over the thoracic wall I had failed to detect clearly the two cardiac sounds owing to the feebleness of the cardiac action, but now both sounds were as distinct as they would have been from a normal heart. They were not, however, the same precisely as the sounds we hear through the thoracic wall; they were duller in character, as if they wanted the resonance which is probably produced by the pleura stretched over the thoracic cavity. At the same time they were loud and were singularly distinct. By moving the tube gently up and down I could get the second sound separately from the first and *vice versa*; but when I had the opening of the tube midway so as to compass both sounds there was not so much difference between the first and second sound as is common to that distinguishable in ordinary auscultation. I was quite prepared for all these modifications of phenomena; they corresponded precisely with what I had learned many years ago when, in combination with the late Drs. Baly and Sibson, I had seen Dr. Halford demonstrate Brien's valvular theory of the cause of the two sounds. We listened at that time directly to the sounds from an opening in the chest wall of a lower animal under anaesthesia, and detected that with such immediate auscultation the sounds were deficient in sharp resonance, and more equable in tone than was common from ordinary auscultation. It was the same now. I counted the beats of the heart very deliberately from the inside of the thorax, seventy beats per minute, the sounds and the pause in proper order and the action perfectly regular. I expected that on withdrawing the tube further out of the œsophagus it would be possible to hear a loud sibilant or vesicular murmur in respiration. In this I was disappointed to a certain extent. It was impossible to catch a murmur, even on a deep inspiration, so distinct as the murmur heard from the chest wall outside.

From these observations I have been led to the new departure in physical diagnosis in which I am anxious others should take part, and I have devoted some time to certain preliminary steps in its development. Briefly it is a means for auscultating on an extensive scale the organs of the body *from within the body*. I shall occupy most usefully the short remaining time at my command, first, by indicating the lines of research in which the plan promises to be most useful; second, the limitations of the plan and, if I may so express myself, the objections to it; and, third, the modes by which it may be improved from this its original start, so as to make it ready, safe and in its broadest sense useful.

Touching the first of these points, the method promises to be useful—I hope very useful—in the diagnosis for which I first applied it. It proved of service to me; at the moment it told me distinctly, in the case I have referred to, that there was no constriction, no induration, at any part of the œsophagus, so that the hearing confirmed the touch, or, rather, corrected it in a manner that could not have been more satisfactory. The advantage will be that stricture may be detected in its very earliest stage—the stage in which, according to my experience (unfortunately an experience specially large in this disease), there is the only chance of doing good by dilatation. The new auscultation may prove also an aid to diagnosis in diseased conditions of the stomach itself. It is certain from the sound I heard from within the cavity of the stomach that there are going on there changes of a physico-chemical kind, leading

to a sort of effervescence that is distinctive in character. It is most probable there are differences of sounds connected with special fermentations, and that by study and experience these differences may become detectable at once by auscultation. Here there is an open field for research in which I have been unable as yet to enter. Again, as bearing on the stomach, the motions of that organ evidently produce sound that will admit of interpretation. A healthy stomach may possibly give forth no sound or it may give forth a definite sound when full of food, with other sounds during various stages of digestion. These are points to be inquired into and will be of curious interest. Still it is certain that in diseased conditions of the stomach a whole series of diagnostic symptoms will be learned, bearing not only on the fermentative action in progress, but on alterations in the walls, and on contractile functions. The stomach, in short, will admit of being sounded like the chest. Scirrhus affecting the stomach should easily be diagnosed by auscultation. Through the stomach it may also be possible to diagnose physically and more correctly than we now diagnose the nature of some pulsating abdominal tumours which are, as they have been since the time of William Harvey himself, a constant source of disagreement amongst physicians. With the terminal of a full-sized œsophageal stethoscope in the stomachic cavity a loud murmur from an arterial source will be detected without the interposition of pressure and an important difficulty in diagnosis removed. A third service that may be rendered by intra-thoracic auscultation is forecast in the observation I have already made respecting the detection of the cardiac sounds in conditions when those sounds are inaudible under the usual method owing to extreme feebleness of the circulation. We are called sometimes to persons in such entire collapse that it is doubtful whether they are alive or dead. The sounds of the heart are imperceptible to the ear through the thoracic walls. Here, then, is an instant and ready method of deciding whether the action of the heart is still in progress. We have a new proof either of absolute death or of continued life. In acute collapse, as after death from chloroform, we not only can institute a good diagnosis in the same manner, but we are half way, by our manipulation, towards assisting to restore life. Through the œsophageal tube, after disconnecting the stethoscopic tubes that go to the ear, we could inject a free quantity of heated water or water with oxygen peroxide into the stomach; or, if we had learned the practice correctly, we could direct a faradaic current upon the heart itself, so as to excite contraction of the right side.

The use of the intra-thoracic method may be turned to account in diagnosis of heart disease and of aneurysm of the large thoracic arterial trunks. Stricture of the œsophagus arising from aneurysmal pressure would be instantly diagnosed. These cases are often most perplexing. The pressure causing the obstruction varies, and no sufficient sign of aneurysmal murmur in the early stages reaches the ear at all times. An auscultator fortunately catches the murmur, another does not, and so contradiction upon contradiction amongst the best diagnosticians occur. By the process of intra-thoracic auscultation this difficulty would be immediately met, the pulsation would come under direct observation, and the precise seat of the pressure would be descended upon. We should hear a pulsating stricture. In heart disease itself the intra-thoracic mode of examination should be of service. By it we ought to be able, in cases of enlargement, to distinguish between dilatation and hypertrophy. The diagnosis of clot on the right side might be made clear by this plan and the differential diagnosis of valvular affection on the right or left cavities ought to be rendered absolute, when we have learned sufficient of œsophageal auscultation to discover the new distinctions of sound that will have to be made, in some cases at least, between the tone of the first and the second sounds, and shall have defined all new lines of distinction between these sounds as heard from within and from without the exterior walls of the chest. The clearest definition by this test should be obtainable also as between pericardial and endocardial friction sound and between pericardial as distinct from pleural friction.

As this is only a preliminary note I must leave untouched the subject of pulmonary auscultation by the intra-thoracic method and also that of pharyngeal exploration. The pharynx is within such easy reach it should admit of more frequent auscultation than lower parts of the œsophageal canal. Its size, too, renders it more accessible. From it we should be able to reach the apices of the lung and the greater part of the air passages from the larynx down to the bifurcation of the bronchi. Exploration of these parts will

be easy when a set of appropriate and convenient exploring instruments have been constructed, and will afford help to diagnosis of changes incident to the apices of the lungs in subclavian, innominate and carotid murmurs, and in thickenings and obstructions of the trachea and larynx.

Having given an outline of what may be gained by intrathoracic auscultation, I shall now refer to the limitations of the plan and to the objections which may be taken to it. I assume at once that this mode of research is not called for when by the ordinary auscultation diagnosis is clear. It may come in usefully in all cases where the œsophageal tube is used for exploration, but it will not be always applicable in instances where it might be useful, owing to the circumstance that many patients are unable to bear the introduction of the tube and that it may sometimes be unadvisable to subject them to it. I met with a patient last week suffering from probable thoracic aneurysm in whose case the exploration would have been most valuable; but the introduction of the tube caused so much retching and straining I was obliged to withdraw the tube before I had explored as fully as I could have wished, although what was effected was sufficient to inform me of the existence of aneurysmal murmur from the left carotid or subclavian. The explorations might also be objectionable in cases of irritable stomach or where there was severe cough or cough with hæmorrhage. I need not dwell any longer on particular points of this kind, since the whole is summed up in a sentence whenever the practitioner feels he can safely and prudently pass a tube into the stomach, then he can bring into practice intrathoracic auscultation.

The third point, the modes in which this method may be improved by mechanical means, opens up a very wide field of inquiry. I commenced my work with the ordinary flexible tube, and up to the present time I have found nothing better than a good-sized tube with a large lateral aperture at the extreme end. I have used another tube charged with several apertures an inch from each other, and this answers fairly well. Apertures are essential in these tubes; if they are not made there is little or no conduction of sound. Messrs. Krohne and Sesemann have been making tubes for me of different materials, and one of metal, of malleable nature, is good in many ways, but I have not yet obtained what is precisely wanted even in so simple an invention as this at first sight would appear to be. The best tube at this moment is the long œsophageal flexible tube with the stethoscope attached as shown to-night.

I leave now this contribution in the hands of a Society to which it has been my high privilege to communicate many of my first thoughts from the very opening of my long career. I would not on any account attach an undue importance to the effort, or look upon it as anything more than an extension of the simple act of the illustrious Laennec, when, in the Necker Hospital one day in 1816, he improvised a stethoscope out of a roll of paper and projected thereon a new science to which there seems to be no end. I put forward this addition, however, without apology, not knowing to what—small as it is at this precise moment—it may lead. In his magnificent eulogy on his master, Cullen, Benjamin Rush said: "Let no fact in medicine, however unimportant it may at first appear, be allowed to pass unnoticed by the public eye; for there are mites in science as well as in charity, and the ultimate results of each are often alike important and beneficial." In that spirit, Sir, I offer to-night, through you and my fellow colleagues of the Society, one more mite to the treasury of practical medicine.

**ST. GEORGE'S HOSPITAL.**—The following scholarships have been awarded for the year 1892-93:—£145 scholarship to Mr. Henry N. Coltart; £50 scholarship to Mr. Frederick G. Peck; £50 scholarship to Mr. John B. Christian. A scholarship of £65 (open to University men) to Mr. Edmund T. Fison and Mr. Arthur Trethewey.

**THE NEW POLICE CONVALESCENT HOME, BRIGHTON.** On Saturday last Princess Christian, attended by Colonel and Mrs. Gordon, visited Brighton for the purpose of laying the memorial stone of the new police convalescent home. Her Royal Highness was received at the station by Mr. T. Cave, Mr. C. B. Woodruff, J.P., Dr. Ewart, J.P. (the mayor), and Mr. Gerald Loder, M.P., and was afterwards accompanied to Bertram-road by an escort of Inniskilling Dragoons, where the stone was duly laid. The building will cost £6000 and will, when completed, accommodate over 600 patients.

## THE RADICAL CURE OF HERNIA, WITH A DESCRIPTION OF A METHOD OF OPERATING FOR FEMORAL HERNIA.

By W. WATSON CHEYNE, M.B. EDIN., F.R.C.S. ENG.,  
PROFESSOR OF SURGERY IN KING'S COLLEGE, SURGEON TO KING'S  
COLLEGE HOSPITAL, ETC.

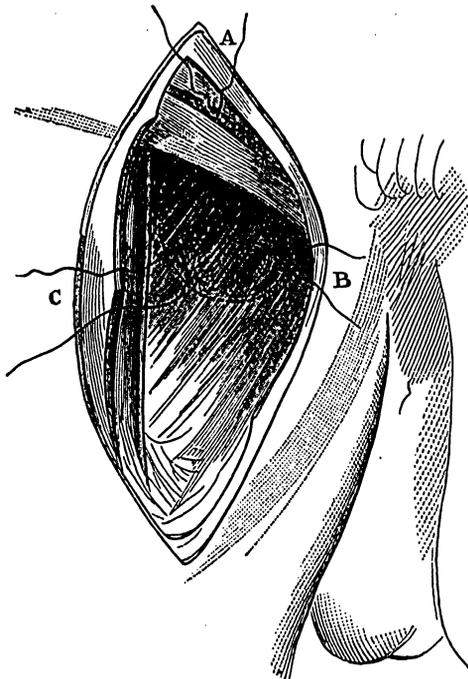

WHILE I wish to say a few words on the method of operating for the radical cure of inguinal hernia my main object in this paper is to describe a method which I put in practice some months ago for the radical cure of femoral hernia. Although the radical cure of inguinal hernia now leaves little to be desired as regards both immediate and permanent results, this is by no means the case with any of the methods which have as yet been described for the treatment of femoral hernia. Practically all the methods for the closure of the femoral canal consist, after tucking up the sac, in the attempt to approximate Poupart's ligament and the fascia over the pectineus. Now Poupart's ligament is a tense band and when stitched down to the pectineal fascia one of two things happens. In the first place, if it keeps down the tension is so great that the stitch very soon cuts its way through the ligament; in the second place, what usually has happened in my experience is that if the pectineal fascia alone is taken up in the stitch it is at once torn off the pectineus and carried forwards to Poupart's ligament, and the stitch soon cuts through the fascia. The result, in my experience, has not been at all certain and not to be compared to the result after the radical operation for inguinal hernia. On thinking over the matter, it seemed to me that the only satisfactory plan would be to turn in some tissue which would fill the femoral canal and at the same time not be subject to any tension. On looking about for material to form a flap to turn into the canal the only available structure seemed to me to be the pectineus muscle. I at first thought of turning up a flap of the pectineal fascia, but it is often very thin, and the cases in which it had been drawn forwards to Poupart's ligament were not on the whole satisfactory, and therefore I came to the decision to turn up a flap of the pectineus muscle itself. Curiously enough, although at the time that I worked out the operation on the dead body (now more than a year ago), and, indeed, at the time I put it in practice, I could find no indication that this idea had occurred to anyone else. I find in looking over the recent numbers of the *Centralblatt für Chirurgie* that on Aug. 20th, Salzer of Utrecht describes a method of turning up the pectineal fascia which he put into practice about the same time that my cases occurred, the guiding idea of which is the same as mine. He, however, uses the pectineal fascia, which I had rejected for the reasons I have mentioned, and which I feel sure will not prove to be satisfactory.

My plan of operating will be evident from the accompanying engravings. After the hernia has been reduced the neck of the sac is ligatured and stitched to the abdominal wall (A in Figs. 1 and 2). A flap is then marked out in the pectineus muscle of sufficient size to fill up the crural canal without any tension, and including the whole thickness of the muscle. The incision in the muscle begins at the inner wall of the crural canal, runs for a short distance parallel to Poupart's ligament and then curves downwards, outwards and upwards (see dotted line in Fig. 1). At the two lowest angles of the flap stitches are passed and tied so as to get a good hold (B and C in Fig. 1) of the muscle. The flap is then peeled up from the bone and the stitches (B and C) are passed through the abdominal wall, B above Poupart's ligament and C just at it. (See Fig. 2.) The result is that the femoral canal is completely filled up with a thick mass of muscle, which soon unites to the sides of the canal; and although its muscular elements may atrophy, a dense mass of fibrous tissue will be left behind. The stitches which I used were Chinese silk of medium thickness. I have operated in two cases by this method and the results are so far perfect; the region of the crural canal remains a hard mass, without the slightest impulse on coughing, and the patient does not wear a truss. I may in a few words mention the notes of these two cases.

**CASE 1.**—This patient, a female, aged forty-seven, was admitted to King's College Hospital on June 20th, 1892. She first noticed the swelling in the right groin three years

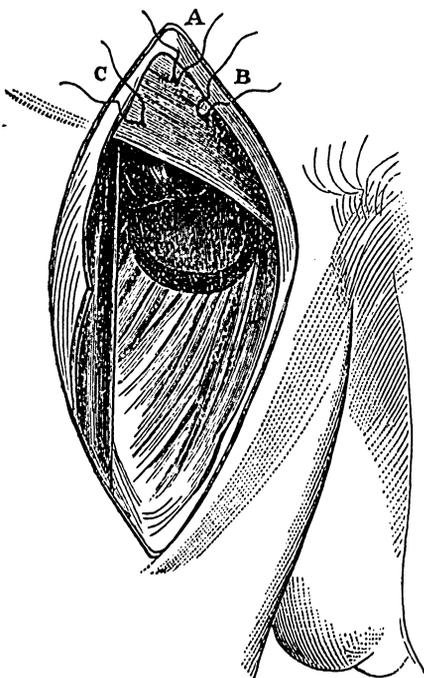

previously, and it has never disappeared; in fact, on the whole, it has increased in size. For the last three months it has been getting much larger and very painful. She also suffers from uterine trouble and ruptured perineum. In

FIG. 1.

the right groin there is a large, elastic, smooth swelling about the size of a large orange passing upwards and outwards from the region of the crural canal and in appearance resembling a femoral hernia. It is very tender and

FIG. 2.

fluctuates, and the skin is reddened over it; there is no impulse on coughing; no signs of strangulation. Various opinions were expressed as to the nature of this swelling, but I concluded that it was an altered sac of a femoral hernia.

On June 21st I therefore made the ordinary incision for femoral hernia and exposed and opened the sac, which I found to contain straw-coloured fluid, the wall being covered with layers of altered blood-clot. On clearing it out it proved, as I had thought, to be an old femoral sac, the communication with the abdomen having been obliterated at the upper part of the crural canal. I then ligatured the neck as usual, cut off the sac and stitched the neck to the abdominal wall. The canal allowed the easy passage of two fingers through it, and this I closed with the pectineal flap as before described. There is nothing to remark about the after-progress of the case. The wound healed by first intention, except at the middle, where a little glairy fluid could be squeezed out at the first dressing. She was kept in bed for about ten days after the wound had healed, and was sent out on July 21st. At that time there was a hard mass to be felt in the neighbourhood of the crural canal and no impulse on coughing. She was told to wear a bandage for a few weeks, and when seen on Oct. 7th the repair seemed perfect and there was no impulse on coughing.

CASE 2.—A female aged forty-five. This patient, sent by Dr. Williams of Wood Green (who also sent the former case), was admitted to King's College Hospital on June 27th, 1892. She has suffered from right femoral hernia for eight years, and wears trusses, but the hernia is always coming down and getting obstructed, and then there is considerable difficulty in returning it. On examination I found a femoral hernia about the size of an egg on the right side, which could only be partially reduced. On June 28th a similar operation was performed to that already described. The wound healed without trouble and she was discharged on July 21st. At that time the parts were quite hard and there was not the slightest impulse on coughing, and when I saw her a few days ago her condition was perfect.

Before concluding this paper I should like to say a few words as to the radical cure of inguinal hernia, an operation of which I have had a large experience. I may say that I have tried practically every method which has been described, and no doubt several of them give excellent results. I now adopt two procedures, according to the nature of the case. Where the hernia is quite small, and where there is no great dilatation of the external oblique muscle, what I do is practically Macewen's operation, cutting off the sac and stitching it up after Barker's plan, but approximating the conjoined tendon to Poupart's ligament with silk stitches after Macewen's plan, and sometimes putting a stitch in the external ring. I may say that in performing this operation, where the external ring is not particularly large, I have found considerable difficulty in getting the hernia needles of Macewen's pattern insinuated beneath the external oblique so as to pick up the internal oblique and conjoined tendon, and in several cases the result of the attempt has been to split up the external oblique for a short distance. That, of course, is quite readily closed again by stitches, but with the view of avoiding it I have altered the shape of Macewen's needle from a curve to an angle (see Fig. 3), and this is then readily pushed up between the external and internal oblique or conjoined tendon after separating them with the handle of the knife, and then, by depressing the point before bringing it back again, it is easy to take up the latter structures. I may say that in these cases Macewen's operation is most satisfactory, and I have never had recurrence except in three or four cases where operations for strangulated hernia or for radical cure by imperfect methods had been previously adopted and where I had mainly scar tissue to work with. I believe that by the adoption of the next plan even these cases would now be successful.

Where the hernia is larger and where the external oblique has become a good deal stretched, I perform an operation which is in its essence Bassini's. After freeing the sac and returning its contents its neck is transfixed, ligatured and stitched to the abdominal wall, in the manner described by Barker. The external oblique is then slit up as far as the internal ring, the incision being carried a considerable distance away from

FIG. 3.

Poupart's ligament. The inguinal canal is thus fully exposed, and the cord is then freed from its coverings as high up as possible. It is held forwards by the assistant, and then a series of stitches are passed through the internal oblique and conjoined tendon (generally four or five in number) above and including Poupart's ligament below, in the manner introduced by Macewen. When these are tied the inguinal canal is completely closed, the only communication with the abdomen being at the point of exit of the cord, which is now above the middle of Poupart's ligament. The cord is now laid on the surface of the internal oblique and the incision in the external oblique is closed by a bootlace suture of fishing gut, sufficient hold of the tendon being taken to render it tense over the cord and only enough room being left at the external ring to allow the cord to escape. It is thus evident that for a hernia to find its way into the scrotum it must push its way through along the cord and then burrow along dense cicatricial tissue for two or three inches till it reaches the external ring. The operation as I have described it is in its essence Bassini's, but it is not carried out exactly as he describes; in fact, it is a combination of various operations. Thus the method of cutting off and tucking up the sac and the use of silk is borrowed from Barker; the principle of bringing the internal oblique to Poupart's ligament behind the cord is Bassini's, but the mode in which the stitches are applied is borrowed from Macewen; the use of silkworm gut for the incision in the external oblique is from Stanley Boyd; the bootlace suture I used myself, but I find that Boyd had also used it.

I have now performed a large number of operations by the former plan and some twenty by the latter, and, while I have lost none, the results are, as far as I can judge, perfect. In none of them, with the exceptions I have already mentioned, is there any tendency to recurrence, and those done by Bassini's method are particularly firm and satisfactory. In view of such results, which have been obtained also by other surgeons, it is curious that many patients with hernia well suited for operation are advised to be content with a truss, and that some surgeons still say that the so-called radical cure of hernia is not really a radical cure. I can only think that the origin of the latter opinion is partly from the observation of operations imperfectly performed and partly because the patients are ordered to wear a truss afterwards. The usual fault committed in the operation is, I think, that the internal oblique and conjoined tendon are not separately attached to Poupart's ligament, but that the stitch is made to include the internal pillar and the conjoined tendon at the same time. The results of that procedure are, so far as I have seen, unsatisfactory. A much better repair of the inguinal canal is got by bringing the conjoined tendon to Poupart's ligament independently of the external oblique. I do not think that it is so much the adhesion between Poupart's ligament and the edge of the internal oblique and conjoined tendon which prevents the recurrence of the hernia as the adhesion between the external oblique and the structures beneath it in a new position, which prevents the conjoined tendon slipping up again and leaving the inguinal canal open. The second reason, I think, is that some surgeons recommend the patient to wear a truss afterwards. This is radically wrong. If the repair is properly accomplished the only effect of the truss will be to cause absorption of the new material thrown out, and I always insist on the patient leaving off all support in about two months after the operation and only wearing a light bandage up to that time.

Welbeck-street, W.

## REMARKS ON THE SCOPE AND ORIGIN OF FIBROID PHTHISIS.

By A. G. AULD, M.D. &c.,

ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY OF GLASGOW.

SINCE the discovery of the tubercle bacillus an immense propulsion and show of stability have been imparted to the theory of the tuberculous origin of the several varieties of phthisis. It is held that of the genus "phthisis" there are several species whose separate features are the outcome of the different reactions which take place between the bacillus and its host. If the parasite flourishes apace and the resulting products get heaped together, and likewise rapidly disseminated through the lung, acute phthisis, com-

monly called "galloping consumption," is produced. If the tuberculous masses are gradually evolved and dependent chiefly on inflammatory products, ordinary caseous phthisis results; while if the tubercles are chiefly and also slowly formed in the peribronchial rather than the alveolar tissues undergo a fibroid metamorphosis, and are likewise accompanied by the growth of fibroid tissue more or less generally throughout the lung, the disease is fibroid phthisis. And it assuredly must be admitted that in this simple and well-ordered scheme of the unity of phthisis there is not only a fascination, but also the illustration of a principle which reigns supreme both in nature and in art.

Now in so far as phthisis pulmonalis is tuberculous there can, I think, be no serious objection taken to this explanation of its various phases; but many at the present time go so far as to affirm that phthisis is synonymous with a local tuberculosis in the lungs, and has no wider signification. This limitation, be it observed, is not made in an arbitrary fashion or for the sake of convenience; far otherwise, for it is held that in all cases which can possibly fall under the designation of phthisis, or, in other words, in all cases which are characterised by the progressive destruction or excavation of a non-malignant pulmonary consolidation, the bacillus tuberculosis indubitably exists. Let it, they say, be conclusively shown that such a destructive lesion can arise and proceed which at no period throughout its whole course is associated with the tuberculous organism, and then the question of the identity of phthisis and pulmonary tuberculosis may be reconsidered. Now this demand, even granting it can be fulfilled, is excessive. For in the case of pulmonary inflammations or consolidations which at a certain period of their course happen to become contaminated with the tubercular bacillus, it is evident that the bacillus, not having originated the disease, can hardly lay claim to an undivided sway. Such, for example, are cases of fibroid phthisis in which the tuberculosis occurs as a late accident of the disease; and if such tuberculosis should be limited, undergo fibroid change, and not very materially alter the regular progress of the signs and symptoms of the malady, the scientific narrowness involved in denominating the affection a tuberculosis of the lungs becomes palpably manifest.

In order to assist in the solution of this problem of phthisis and tuberculosis it becomes almost imperative at the present time that any case which possesses unusual features, such as the absence of bacilli from the sputum with signs of much mischief in the chest, should be carefully noted. In particular post-mortem examination of such cases should be thoroughly carried out, for the failure to find bacilli in the sputum during life is by no means conclusive as to their absence from the lungs. With this end in view I submit a short account of a case which made a deep impression on all who had the opportunity of seeing it at the post-mortem examination, and the features of which during life have been pretty accurately obtained. It is that of a young man aged thirty, by occupation a tinsmith, who was received into the infirmary in June, 1886. He looked pretty well, though somewhat emaciated, and his family history revealed no phthisical taint. He dated his illness from an attack of inflammation of the lungs ten years previously. Ever since, more or less cough had troubled him; this cough had become constant and attended with a yellowish spit, occasionally blood-streaked, for the last four years. Two months before his admission to the hospital he observed that the expectoration was acquiring a disagreeable odour. He complained of a pain in the chest to the right of the sternum, and his expectoration was profuse, muco-purulent and of a somewhat fetid odour. His respirations numbered 22. On inspection the right side of the chest was flattened and expanded but feebly. Palpation revealed general dullness over this lung, and the respiratory murmur is described as much deficient. The left lung was found to be practically normal; the other organs normal. The temperature hovered irregularly between 99° and 103°. This incomplete note is supplemented by the statement that the patient left the hospital after six weeks, greatly improved and with the expectoration in a much healthier condition. The patient again came under observation, this time in the Western Infirmary, after an interval of four months. He had much cough and dyspnoea and a yellowish expectoration of an offensive odour. The left lung had now become involved. Retraction, dullness and tubular breathing existed over the apex. Crepitations were heard in the supra- and sub-scapular regions. The respiratory murmur was impaired throughout and tubular breathing was likewise noted at the base. Dullness on per-

cession and hollow breathing existed generally over the right lung, with crepitation at the base and vocal fremitus markedly increased, especially over the subclavian region. The patient was rather emaciated and nocturnal perspirations were profuse. A hectic flush appeared at times, and there was clubbing of the fingers. In short, the classical signs and symptoms of advanced phthisis pulmonalis were exhibited to a marked degree. But the patient improved, left the hospital after a few weeks' duration, and was not heard of for four years, when he returned to die a few days after admission. At this time the sputum was profuse and mucopurulent, but not fetid, and careful examination completely failed to discover in it any tubercle bacilli. At the post-mortem examination conducted by Dr. Coats, the right lung had to be dissected from the chest wall. It was the seat of several cavities. One was huge, extending from apex to base, and was seven inches in length and four in breadth. It was lined throughout by a perfectly smooth, fibrous membrane, considerably sacculated, and reflected at several points over bridges which stretched across the cavity. This large cavity communicated with a smaller one in the posterior aspect above, and an isolated cavity, two inches and a half in diameter, existed posteriorly below. All these cavities were quite empty, quiescent and lined by smooth, fibrous membranes. Hardly any lung tissue was left and no trace of active disease could anywhere be seen. This specimen is preserved in the Infirmary museum. The left lung was united to the chest wall by adhesions of cartilaginous consistence, especially at the apex. The upper lobe was somewhat shrunken and consisted of dense fibrous tissue of a dark grey colour. In the midst of this tissue were frequent collections of a pultaceous and calcareous matter; the rest of the organ was the seat of apparently recent lobular condensations and was otherwise oedematous. The other organs were healthy. Careful microscopical examination of this lung made both by Dr. Coats and myself revealed entire absence of tuberculosis. The indurated upper lobe contained condensed and partially cretified pus, while the lobular condensations were composed of a dense fibrinous exudation which filled both bronchi and alveoli.

Without dwelling at length on this remarkable case, will it not at once be conceded that it affords a most striking illustration of the degree to which destruction of the lungs may proceed without the demonstrable presence of tuberculosis? What objections or arguments can be adduced against its non-tuberculous nature? Suppose it be said that tuberculosis may have existed at some time, but had become quiescent or disappeared. Now if the tuberculosis had become quiescent, so would the symptoms of the disease, but the patient died of a disease other than tuberculosis. Again, seeing that the right lung was the seat of disease to begin with, how is it that no remains of old tuberculous disease was discovered in it? By no subterfuge can the conclusion be evaded that this was a case of non-tuberculous phthisis. And we are therefore warranted in believing that there are two varieties of fibroid phthisis—one which is either complicated with or originated by a tuberculosis, and another which is not associated with that neoplasm, or, in the words of the distinguished physician who has done so much to elucidate this subject, there is a bacillary and a non-bacillary fibroid phthisis.<sup>1</sup>

I here wish to draw attention to a confusion of terms which has centred round this lesion. Some regard fibroid phthisis as synonymous with Corrigan's cirrhosis, interstitial pneumonia, chronic pneumonia &c. The late Dr. Wilson Fox described under the title of "chronic pneumonia" a large number of chronic inflammatory lesions differing both in their origin and progress. Some originated in acute pneumonia, others in broncho-pneumonia, others in pleurisy and probably a few in bronchiectasis. A simple progressive interstitial pneumonia akin to cirrhosis of the liver or kidney he could find no evidence of, while the existence of an idiopathic fibroid change in the alveolar walls independently of inflammatory action (the "fibroid degeneration" of Sutton) he denied. This chronic pneumonia, according to Fox, "is commonly unilateral; it is frequently associated with dilatation of the bronchi and it tends either through ulcerations proceeding from these or from secondary inflammation of the indurated tissue to give rise to cavities in or gangrene of the lung."<sup>2</sup> As has previously been mentioned, probably many of Fox's cases would now be regarded as tuberculous,

but some assuredly are not, and I would therefore venture to suggest that the terms "chronic pneumonia" and "interstitial pneumonia" should receive a more limited meaning than they have hitherto possessed. If the term "chronic pneumonia" were employed as signifying a simple fibroid consolidation in the lung, while fibroid phthisis were regarded as signifying the accession and course of destructive changes in such a lung, this leading to cavities, a gain would be made in the matter of nomenclature. Moreover, it is scientifically inaccurate as well as an injustice to the patient to style a simple fibroid consolidation "phthisis."

A summary of the various modes of origin of such conditions as ultimately assume the characters of non-tuberculous or simple fibroid phthisis may not be amiss here. Regarding chronic pneumonia as a generic term, and to represent the pre-phthisical stage of the disease; it may be held to embrace cases which originate more or less definitely and acutely and likewise a group of cases which are more or less chronic from the first. Of the latter class the existence of a primary cirrhosis of the lung, resembling renal cirrhosis, is held by many authorities, and it is certainly the characteristic lesion of pneumoconiosis. More commonly, however, chronic bronchitis, with peri-bronchitis leading to localised lobular indurations and bronchiectasis, form the starting point of the disease. In other cases bronchiectasis appears early, and the stagnant secretions cause circumscribed inflammation round the dilatations, ending in induration. More or less pleurisy is frequently associated with these lesions which form the basis of the most classical type of fibroid phthisis. Of the other or acute class of cases pleurisy and acute broncho-pneumonia are most frequent. Some doubt whether a simple pleurisy can originate an induration of the lung, but the evidence is in favour of such a sequence, for inflammatory changes in the lung are frequently traceable to progressive ingrowth from the pleura. In the last place, and least frequent, is acute pneumonia. Evidence has lately been accumulating in favour of its occasional, though very rare, issue in induration. Some confusion has arisen here because two different forms of induration have been observed to occur after this affection. In one of these the lung appears much shrunken, either in whole or in part, bronchiectatic and altogether resembling Corrigan's cirrhosis. Now in such cases it will invariably be found that the lesion is due to pleurisy which has complicated and outlived the pneumonia. The other or genuine pneumonic induration has individual features of its own totally different from those presented by any other chronic affection of the lungs, and hence I claim that it is justly entitled to a separate designation. Dr. Coupland, in this country, was the first to put on record the microscopical appearances in this affection, which consist in a fibroid transformation of the pneumonic exudation. Working further at this subject led me to suggest the name "fibroid pneumonia" for it. It shows but slight bronchiectasis, but may issue in fibroid phthisis through intercurrent inflammation or necrosis of the indurated tissue.

Glasgow.

## THE TREATMENT OF THE PERITONEUM IN ABDOMINAL SURGERY.<sup>1</sup>

By W. A. MEREDITH, M.C. EDIN.,  
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE attainment of success in abdominal work, as in any other department of surgery, must naturally in great measure depend upon the training and special experience of the individual operator. But apart from these general factors the observance of certain important details in relation to the methods of treatment employed undoubtedly tends to influence the proportion of successful results obtained in any given instance. Surgical procedures implicating the peritoneum may in some degree be considered as regulated by different laws from those which guide the surgeon in dealing with other serous cavities. This fact is dependent not alone upon the large extent of the peritoneal surfaces, with their numerous folds and recesses, but, further, upon the peculiar vital properties which characterise this membrane as regards both its special structure and its intimate relation to the main excretory organs of the system, through the ready channel afforded by the subjacent lymph and bloodvessels.

<sup>1</sup> Lecture on Fibroid Phthisis, by Sir Andrew Clark, THE LANCET, July 2nd, 1892.

<sup>2</sup> Diseases of the Lungs and Pleura. Edited by Dr. Coupland, p. 412.

<sup>1</sup> A paper read at the Medical Society of London on Oct. 23rd, 1902.

In evidence of the enormous powers of secretion and excretion possessed by the peritoneum, so long as its epithelial surface is comparatively intact, one has but to consider the readiness with which effusion of so-called ascitic fluid takes place as a result of interference with the return of blood through the portal system; and, again, the equally wonderful rapidity with which such effusion may disappear upon the re-establishment of the normal balance of circulation within the vessels underlying the serous membrane; whether as the result of removal of the original hepatic obstruction, or as a consequence of relief to the vascular engorgement obtained by derivative action through the renal and intestinal excretories.

With these facts in view, and therefrom considering the peritoneum in the light of a huge lymph sac, one cannot, I think, too highly estimate the practically unlimited powers for good as for evil which it possesses in relation to operative measures involving its cavity. From such a standpoint as this it seems to me that success in abdominal work, apart from the general factors already alluded to, may be said to largely depend upon the attainment by the surgeon of three main objects which should be kept constantly in view when dealing with the peritoneal cavity.

First of these three I will place "avoidance of the introduction into the serous cavity of any septic or potentially septic material," comprising under this latter denomination any substance or fluid which may, under favouring circumstances, afford a protective nidus or medium for the subsequent development of organisms within the peritoneal sac. It may, I believe, be definitely asserted that the surest and most effective protection against the risk of such introduction of mischief from without during abdominal operations lies in the rigid routine employment of antiseptic—preferably carbolic—lotions for sponges, ligatures and instruments, as well as for the hands of the operator, his assistant and nurses. While expressing this opinion, the truth of which is to my mind absolutely certain, I am fully prepared to admit the possibility of the attainment in skilful hands of good results without the use of any antiseptics whatever during intra-peritoneal operations, providing always that scrupulous cleanliness of procedure be observed, and that the recognised methods of flushing and subsequent drainage of the abdominal cavity be followed in suitable instances. But, at the same time, I have no hesitation whatever in stating that a surgeon who thus trusts to the use of plain water as a substitute for carbolic lotions unwisely neglects one of the surest safeguards against septicæmia, and that, although he may for a while secure good results, his work in the long run must inevitably suffer from such omission. The explanation of this fact is not far to seek. It is not possible, even with the strictest use of antiseptic methods, to entirely banish all risk of septicæmia from abdominal work, since one is constantly exposed to meeting with cases where the poison in an active or potentially active state is present within the peritoneal cavity before operation—e.g., ovarian cysts with septic contents as a result of previous tapping, putrid gestation sacs, tubes distended with puriform fluid, pelvic abscesses &c. Under such conditions a free use of antiseptics with the object of minimising the risks of subsequent mischief by weakening the already existent germs of infection, and thus rendering them an easier prey to the destructive power of the leucocytes, offers indisputable advantages over those afforded by the employment of plain water for mere cleansing purposes. A further advantage possessed by a Listerian operator—one more readily appreciable, perhaps, in hospital than in private practice—is the degree of protection afforded by the routine use of antiseptics against the recurrence of disaster after a death from septicæmia. Anyone who will take the trouble to examine the record contained in Sir Spencer Wells's work on "Ovarian and Uterine Tumours" (London, 1882) of consecutive ovariectomies performed previously to his adoption of the antiseptic method in 1879, cannot fail to observe that a death from septicæmia, occasionally succeeding to a series of as many as twenty-five recoveries, was almost invariably followed by a more or less interrupted succession of fatalities attributed to septic causes. Such a noteworthy fact—accountable for only by the transmission of infection from one case to another, whether through sponges, silk, instruments or by the hands of the operator or nurses—constitutes, to my mind, one of the strongest arguments in favour of antiseptics in abdominal work, since we know that by their use we can surely lessen, if we cannot altogether avoid, the risk of thus unwittingly conveying infection from one patient to another.

Turning now to the *second* of the objects to be kept in

view by the abdominal surgeon, I would define it as "avoidance of the infliction of any unnecessary injury to the peritoneum whereby its vital properties may be impaired." It was long ago pointed out by Sir Joseph Lister that any suspension of vital activity in a tissue as the result of injury leads to paralysis of its special functions and to consequent impairment of its ability to resist the entrance of parasitic organisms. This observation is one of very grave moment when considered in relation to its bearing upon so delicate a structure as that which characterises the serous membrane lining the abdominal cavity, and in confirmation of its importance we have the statement of so high an authority on this subject as Professor Watson Cheyne, to the effect that "one of the conditions favouring the development of peritonitis as a consequence of the introduction of cocci into the peritoneal cavity is an abnormal state of the serous membrane whereby its absorptive power has been diminished—as, for example, by the action of any substance which weakens, or kills the serous tissue, and thus provides a suitable soil for the penetration of the cocci."<sup>2</sup>

Now depression of vitality may be either general or local; and any method of treatment tending to induce it in either direction should, in my opinion, be sedulously avoided. This brings me to the question of the employment of the carbolic spray in abdominal work. I have myself entirely given up the spray since the end of 1888; and, so far as I know, its use has now been abandoned by the leading abdominal surgeons in this country, with the sole exception of Mr. Thornton, who, I believe, still employs it in peritoneal operations. Were it not for this latter fact I should not consider it necessary to further allude to this subject of the spray, but under the circumstances I deem it well to briefly note my own chief objections to its use. In the first place, we have no proof whatever that the carbolic spray can safeguard us against the introduction of septic mischief into the open abdominal cavity otherwise than by maintaining a form of constant antiseptic irrigation for moistening the exposed surface of the patient's abdominal wall, as well as the hands of the operator, his assistant and nurses. While fully admitting its usefulness in this respect, I am convinced that the object in view can equally well be attained by the exercise of ordinary care on the part of a Listerian operator in the way of sponging and frequent ablutions; and that he may thus secure all the advantages derivable from the use of carbolic acid without exposing his patient to the risks entailed by the chilling properties of the spray. These latter constitute my own chief objection to its employment. Anyone who has stood for an hour or more assisting with bared arms in the performance of an abdominal section under a steam spray can form for himself a tolerably accurate estimate of its powers in this direction; and thus in some measure conceive the extent of its depressing influence upon the vitality of the patient, a portion of whose abdominal wall is of necessity exposed to the cold moist blast. Such exposure during prolonged operations, especially in wintry weather, undoubtedly entails serious risk of death from shock in the case of feeble, elderly patients; while, short of this, it not infrequently interferes gravely with the progress of convalescence by originating troublesome chest complications. In addition, however, to the depressing influence of the steam spray upon the general vitality of the patient, one must further take into account its direct action upon the peritoneum itself during the removal of large solid tumours necessitating a lengthy abdominal incision, or in cases of ovarian or other cysts complicated by the presence of extensive adhesions. Under such circumstances I am convinced that prolonged exposure to the chilling and irritating influence of the carbolic spray—while necessarily increasing the general depression—undoubtedly further tends to temporarily impair the vitality of the serous membrane itself over areas of greater or less extent; and, by thus lessening its powers of absorption, to induce the abnormal condition above referred to as favouring the penetration of cocci and the consequent development of peritonitis. A still more definite, but commonly unrecognised, source of injury to the peritoneum, leading to more or less extensive impairment of its vital functions, arises from the performance of what was formerly known as the "toilette du péritoine"—a procedure commonly involving assiduous and prolonged sponging of the abdominal cavity in cases of extensively adherent or ruptured cysts.

In my early operating days I naturally followed in this

<sup>2</sup> Brit. Med. Jour., vol. 1, 1888, p. 624

regard the example set me by my two senior colleagues at the Samaritan Hospital, both of whom were then extremely careful in thus cleansing the peritoneal cavity at the conclusion of an abdominal operation. Such treatment, in complicated cases, was usually followed within forty-eight hours by a smart rise of temperature to 102° or over, frequently necessitating the use of an ice cap for its reduction. When I began in 1882 to assist Sir Spencer Wells, who then operated with full antiseptic precautions in every respect similar to those employed in the Samaritan Hospital, I soon became impressed by the fact that complicated cases of ovariotomy, where no attempt was made to sponge away the mixture of blood and other fluids remaining in the pelvic cavity at the conclusion of a troublesome operation, not unfrequently recovered with but very slight disturbance of either temperature or pulse, although no drainage-tube was used. Such results following treatment so opposed to the routine practice in the hospital at that time puzzled me somewhat, until I formed the conclusion that avoidance of unnecessary irritation of the serous membrane might have something to do with them; and, as time went on, my views in this direction were materially strengthened by watching the results obtained in cases where the abdomen was washed out with warm water instead of being cleansed by sponging. I have now myself employed this treatment of "flushing" with increasing frequency for over four years past, and am constantly more and more impressed by its value—as a ready and efficient means of cleansing the peritoneal cavity with the minimum infliction of damage to the delicate epithelial surface of the serous membrane—a fact which from my point of view constitutes one of its greatest advantages. As a firm believer in the importance of asepticism I need hardly add that I consider it advisable always to employ for this purpose water which has been previously sterilised by boiling, as the surest means of avoiding the introduction of possible mischief into the peritoneal cavity.

Passing on now to a brief consideration of the *third* of the three objects to be aimed at by the abdominal surgeon, I define it as the "promotion of the subsequent removal by natural or by artificial means of any fluids remaining in the pelvic cavity at the conclusion of the operation." By the term "natural means" I would imply the early re-establishment and maintenance of the renal and intestinal eliminatory functions which play so large a part in promoting the absorption and subsequent excretion of peritoneal effusions. Without dwelling on this subject I will here merely refer to what I believe to be the extreme inadvisability of the routine administration of opium after abdominal operations, owing to the restraining influence thereby exercised upon these functions; while further noting the value of repeated small doses of salines administered not with a view to relieving any tendency to obstructive bowel difficulty, but merely as promoting renal and intestinal excretion. By the artificial or mechanical means above mentioned I of course allude to drainage of the pelvic cavity as best effected by the ordinary glass tube whence the accumulated fluid is withdrawn at stated intervals. An objection formerly raised against this method of drainage was based on the statement that it was liable to be followed by a ventral hernia at the seat of insertion of the tube. Such a mishap has fortunately been extremely rare in my own experience, and I regard its occurrence as indicative of too prolonged retention of the tube. In my opinion all the good derivable from drainage of the peritoneal cavity proper is commonly attained within the first twenty-four to forty-eight hours after operation, and any further prolongation of the process is but rarely advisable. My own invariable rule is to remove the tube whenever the entire amount of fluid accumulated during the previous twelve hours is found not to exceed two to four drachms, and this quite irrespective of whether the serum then withdrawn be bloodstained or not.

In support of the views here expressed I will now very briefly summarise the results obtained in my practice from December, 1888, when I abandoned the use of the spray, to the end of July, 1892. During this period of about three years and a half the total of my abdominal operations amounted to 201; but in eighteen of these, chiefly cases of pelvic abscess, the serous cavity proper was not invaded,<sup>3</sup> and I shall consequently confine my remarks to the remaining 183

operations, all of which implicated the peritoneum. Of this number, forty-two were undertaken for disease either unconnected with the pelvic organs or, when so connected, of such a nature as not to admit of complete extirpation. Thirty-three of these patients recovered, and the remaining nine died from causes shown in the accompanying table.

TABLE I.—*Peritoneal Operations:*

No.	Nature of disease.	Cause of death.
1.	Double intra-peritoneal abscess (of septic origin).	Shock, within six hours.
2.	Cancer of both ovaries (partial operation).	Shock, within four hours.
3.	Advanced tubercular disease of peritoneum.	Exhaustion, on twelfth day, from persistent diarrhoea.
4.	General abdominal cancer.	Exhaustion, on eighth day.
5.	Pelvic cancer.	Exhaustion, on fourth day.
6.	Intra-peritoneal abscess (? of tubal origin).	Exhaustion, on seventh day.
7.	Retro-peritoneal sarcoma.	Exhaustion, on third day.
8.	Cholecystotomy.	Perforation of intestine, on twenty-eighth day.
9.	Hydatid disease of liver.	Cerebral disease, on eighth day (? hydatid).

The remaining 141 peritoneal operations were performed for disease originating in the uterus or its appendages in the following proportions and with the results here shown—viz., 137 recoveries and 4 deaths.

TABLE II.—*Peritoneal Operations.*

Eighty-four cases of ovarian tumour.	....	One death from pneumonia on thirteenth day.
Fifteen cases of chronic inflammatory disease of one or both uterine appendages.	....	One death from intestinal obstruction on eighth day.
Five cases of ruptured tubal pregnancy with intra-peritoneal hæmorrhage.	....	One death from exhaustion within five hours.
Thirty cases of supra-vaginal hysterectomy for fibro-myoma.	....	One death from shock.
Seven cases of removal of the uterine appendages for fibro-myoma.	....	No death.

This series of 141 operations performed on the lines indicated in my paper, with a mortality of under 3 per cent., may, I think, be taken as affording some evidence of the correctness of the views advocated with regard to the treatment of the peritoneum in abdominal work; and, in conclusion, I would here venture to express the hope that the record of my experience in this direction may tend to promote a fuller recognition of the enormous powers for good as for evil possessed by the serous membrane in relation to surgical procedures involving its cavity.

Manchester-square, W.

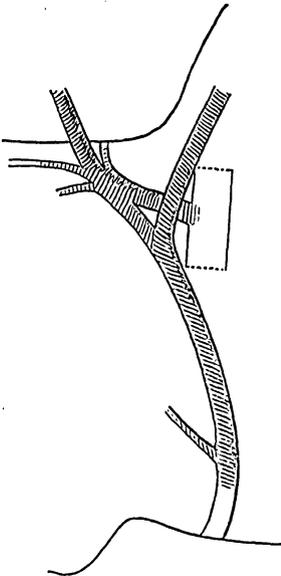

## ALVEOLAR ABSCESS; PYÆMIA; EXCISION OF THROMBOSED VEINS; DEATH.

By W. ARBUTHNOT LANE, M.S., F.R.C.S.,  
ASSISTANT SURGEON TO GUY'S HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN.

H. R.—, aged four years, was admitted into Guy's Hospital on Aug. 18th, 1892. He was suffering from a swelling over the left half of the lower jaw, which commenced with toothache about a week before. Five days previously an abscess burst into the mouth, and since that time the swelling had diffused itself more extensively. His temperature on admission was 105.4°. There was an alveolar abscess about a carious second molar tooth. This was removed and the abscess cavity scraped and thoroughly cleaned out under an anæsthetic. The boy became jaundiced and suffered from recurring rigors on the 19th, 20th, 21st and 22nd. On the 22nd I saw the child for the first time and decided to make an attempt to stay the progress of the condition by excising any thrombosed veins that might exist and by clearing out the inflamed bone and other tissues. At this period the patient was deeply jaundiced and the liver much enlarged; he had, however, no apparent renal complication, though there was strong presumptive evidence of patches of pulmonary mischief. The skin was turned back from the anterior triangle and sterno-mastoid when the external jugular vein was exposed, and was found to contain a purulent material to within half an inch of its lower end.

<sup>3</sup> The group of eighteen operations above referred to included seventeen recoveries and but one death, which resulted from exhaustion due to diffused pelvic suppuration of some two years standing previous to surgical interference.

There the clot was black, and below this point, at its junction with the subclavian, the external jugular vein was tied and divided. The walls of the vein, with the immediately adjacent tissues, were inflamed and thickened. The external jugular vein was then followed upwards into the parotid and forwards to its junction with the facial vein. The latter was dissected out and was found to be filled with a firm pale clot. The branches of the facial vein, with the exception of the distal portion of the submental, were filled with clot of the same character. The common facial vein was also thrombosed, the clot extending for a slight distance into the lumen of the internal jugular vein, which was exposed for a distance of half an inch above and below the point of entry of the common facial vein, and after it had been ligatured at these two points the intermediate portion was excised. Having removed all the thrombosed veins thoroughly on their proximal side their distal distribution was treated in as effectual a manner as possible, though it was obvious that this portion of the operation was not as perfect as the rest. The abscess cavity and bone were then cleaned thoroughly and plugged with iodoform. During the course of the operation many inflamed lymphatic glands were removed. The patient seemed better on the day following the operation. The jaundice disappeared almost if not entirely by Aug. 25th. The next day

This diagram illustrates the extent of the thrombosis and the several veins which were removed at the operation. The transverse striation represents the thrombosed area of vessel.

it was found that the wound in the neck, whose edges had apparently healed and were devoid of any redness, contained a quantity of yellowish pultaceous material. This was all carefully removed and the wound was thoroughly washed out and packed with iodoform and gauze. He had a gradual rise of temperature to 105.4° on the 23rd, but after that it remained at between 101° and 103° till his death. He had no rigor. The child gradually got worse and died at twelve o'clock on the night of the 26th. At the post-mortem examination it was found that the thrombosed veins had been removed very effectually as far as their proximal distribution was concerned, there being no evidence whatever of thrombosis. There were, however, a number of abscesses in the lungs and liver. These had without doubt been produced by septic emboli at a period antecedent to the operation, which was obviously performed too late. Though the result in this case was unsatisfactory as far as the life of the patient was concerned, it was, on the other hand, most satisfactory and instructive as showing that the method of excising septic thrombosed veins is as effectual in staying a pyæmic process originating in the lower jaw while it is as yet local and uncomplicated by secondary abscesses as it is a more definite and localised thrombosis of the lateral sinus due to disease of the middle ear.

#### WESTMINSTER HOSPITAL.

##### SUPRA-PUBIC CYSTOTOMY FOR CALCULUS.

(Under the care of Mr. R. DAVY.)

THE following account of a method of performing the supra-pubic operation for the removal of a stone from the bladder of the male has one or two points worthy of attention. The performance of the operation without the use of the rectal bag, and without previous distension of the bladder by injection, appears to have been rendered easy and safe by means of the sound described by Mr. Davy. There is no doubt that with the use of this sound the operation was done in less time than is usually required, and therefore was of less severity—a fact of great importance, especially in men of advanced age, for the introduction and filling of the rectal bag and the injection of fluid into the bladder cannot be hurriedly performed without considerable risk. In this case the condition of the urinary passage was such as to have rendered the manipulation of a lithotrite or its introduction difficult, and the danger of bruising the parts, with subsequent swelling and possibly retention, of serious moment. For the notes we are indebted to Mr. H. De Renzi, house surgeon, and Mr. Forsayeth, dresser.

J. R—, aged sixty-three, by occupation a carpenter, was admitted into the Westminster Hospital on Aug. 2nd, 1892, and discharged on Aug. 30th. Twenty years ago he spent six months in Derbyshire, but usually has lived in London. In March last he was knocked down by a tram-horse; the same evening he experienced pain in passing his urine, and a week afterwards he had hæmaturia, sometimes in clots, at other times intimately mixed with the urine. Forty years ago he had gonorrhœa, and since his fall he had suffered from a difficulty in micturition, necessitating the constant use of a catheter. Pain at the bladder and scalding around the anus have been increasing of late. On Aug. 6th, on sounding, a stone of medium size was detected. The abdominal wall was normal and the patient fairly nourished, there being no excess of fat in the subcutaneous tissue. The urine was strongly alkaline, sp. gr. 1015; half albumen was found, and blood, pus and mucus were present. On the 9th supra-pubic cystotomy was performed by Mr. R. Davy. Neither the bladder nor rectum was distended. A conical probe-pointed sound was used, with a groove on its concavity and a hole at its tip. A medium-sized stone was extracted, measuring two inches by an inch and a quarter, weighing seventy-five grains, and composed throughout of soft phosphatic material. The mucous membrane of the bladder was inflamed and sacculated, the No. 4 sound being sufficient to bring the bladder wall well forward after the incision of the abdominal parietes. A silver drainage-tube was passed into the bladder and left in. It appeared that the obstruction to the outflow of urine was due to thickening and hypertrophy of the prostate and spasm of the muscles of the urethra. On the 11th the patient passed urine naturally and the drainage-tube came away. On the 19th he was well, and on the 30th he was discharged cured.

*Remarks by Mr. DAVY.*—The supra-pubic operation, in my opinion, was the best suited for this man, and for these reasons: (1) Crushing was out of the question on account of the difficulty in manipulating or even passing instruments in the urethra of the patient; (2) the high operation, on anatomical grounds, wounds less important structures than those injured in median or lateral operations. In this case neither bladder nor rectum was artificially distended. I wished to operate on the bladder as I found it; as a rule, I have operated with the bladder partly full of water. There is neither difficulty nor danger in operating without distension if the surgeon bears in mind that the bladder is situated for this intent post-symphysially. I can recall more than

one case where the peritoneum has been injured, although fluid distension had been practised, and students not infrequently puncture the peritoneum on the dead body in performing supra-pubic cystotomy, unless the teacher points out this danger and its remedy with emphasis. Mr. George Pollock, who was present at the operation, has introduced a very pronounced curve at the end of the sound, which allows the tip to hook round the symphysis and elevate the bladder wall at the same time. I can testify to the facility given by his instrument in the performance of the operation, and it seems to be preferable to the sonde à dard advocated by Frère Jacques of Orleans. It is satisfactory to note that the urethral obstruction has benefited by the removal of spasm caused by the stone in the bladder. The patient passes his urine now in a normal stream.

### SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

COCYDYNIA; EXCISION OF COCCYX.

(Under the care of Mr. LUCY.)

THERE are many conditions for which it may be necessary to excise the coccyx, but we rarely meet with any of them in practice. The patients usually give a history of injury to the part, which on examination is found to have sustained fracture or displacement, or the injury may have led to a chronic inflammation of the bone or joint or to necrosis of the bone. The formation of a tumour or a congenital elongation of the bone may necessitate excision. There is also a group—of which the following is an example—in which after removal no abnormal change in the bone is found. It is difficult to diagnose these cases of coccydynia from hysterical or reflex cases. The condition is somewhat rare in men. Descriptions of the operation have been published in THE LANCET from time to time. We may instance cases under the care of Mr. Whitehead<sup>1</sup> and Mr. Odell,<sup>2</sup> and an interesting letter by Dr. Nott.<sup>3</sup>

J. M.—, aged sixty-three, single, cook, was admitted on Feb. 4th, 1892, complaining of great pain in the lower part of the back when sitting down, which had been present for over a year. A few years ago she slid off a table and hurt "the bottom of her spine" on a tiled floor. She had no pain on walking or on defecation. There was a small swelling the size of a marble to the right of the tip of the coccyx and presenting a small dimple on the surface. The coccyx was freely movable forwards at the sacro-coccygeal joint, the movement causing the patient intense pain. She also had a slight anal fissure and an intero-external hæmorrhoid. So, thinking that the neuralgic symptoms might be due to the latter, she was given chloroform on Feb. 12th, and the sphincter was stretched and the hæmorrhoid removed by crushing. She quickly got well from this operation, but the severe pain on sitting persisted; therefore, on Feb. 26th she was again anaesthetised. A longitudinal incision was made over the coccyx down to the bone, the periosteum was divided and separated by a raspator and the coccyx removed. At its tip there was a small dermoid cyst containing sebaceous material, which was dissected out. Hæmorrhage was pretty brisk from several small arteries in front of the coccyx. The wound healed by granulation. She got up on March 30th, the wound being quite sound, walked on April 9th, and left the hospital on April 26th, being able to sit comfortably without any pain at all. She was last seen on May 26th, three months after the operation, the wound was soundly healed, and she was back at her work, was quite free from pain on sitting down, and was putting on flesh.

### CLINICAL SOCIETY OF LONDON.

*Macrocheilia treated by Electrolysis.—Subcutaneous Suture of Patella.—Transverse Fracture of Patella.—Raynaud's Disease.—Amputation of Arm for Lymphatic Œdema in cases of Breast Cancer.—Congenital Deficiency of a portion of Chest-wall.—Sinus in Loin connected with Posterior Mediastinal Abscess.—Sarcoma of Skin.—Complete Erasion of Ankle-joint.*

A "CLINICAL" meeting of this Society took place on Oct. 28th: the President, Sir Dyce Duckworth, in the chair.

Mr. ARBUTHNOT LANE showed a man, aged twenty-eight, who was employed at the General Post Office and who three years and a half ago struck his upper lip; this was followed by very great swelling, and two months later the lower lip also became swollen. The swelling was hard and brawny, and after a short time the cheeks became hypertrophied in the same way. Having refused to yield to other treatment, electrolysis was employed on several occasions, and the lips had returned to their normal state, except that the lower lip was still a little larger than it should be.

Mr. BARKER showed a man, aged twenty-five, a porter, on whom he had performed subcutaneous suture of the patella. The wire still remained round the bone, which was united by a strong fibrous band. He was on a splint for three weeks after the operation and left the hospital at the end of a month. It was done in March, 1891, the fracture being transverse and the wire for the suture being one-sixteenth of an inch thick. The patient had been doing very hard work since, and the movements were very free. Since then he had operated on a second case, and he had allowed him up without a splint at the end of a week, and he was able to walk freely in six weeks.

Mr. PAGE also showed a case of transverse fracture of the patella in a patient aged thirty-three, in which subcutaneous suture, according to Mr. Barker's method, was done on May 18th, 1892. The man was a coalheaver by trade, and the result was good, as he thought that the union was bony. He had since treated in a similar manner a case of compound fracture of the patella, which had also done well; but in both cases he had used silk and not wire.

Dr. F. LITTLE showed a girl employed at a florist's, who was the subject of Raynaud's disease. When aged nineteen both the hands and feet began to feel cold, but this was unaccompanied by pain. Ulceration then commenced around the nails of all the fingers except the little fingers, and since then shortening and clubbing of the terminal phalanges had occurred. The nails of the toes had not been affected. There was nothing in the family history to throw light on the case. The body temperature was normal but the surface temperature of the hands was 65° F. There had been no hæmaturia or hæmoglobinuria. The treatment consisted in the exhibition of nux vomica and steel, together with the local employment of galvanism.

Mr. BLAND SUTTON showed two cases of amputation of the arm for lymphatic œdema in cases of cancer of the breast. The first was a woman aged forty-three, who, two years and a half ago, had the right breast removed for cancer. Six months later some knots began to form in the skin of the scar, and later the whole of the neighbouring parts were invaded *en cuirasse*. The arm then became much swollen and œdematous, being three times its normal size, extremely heavy, and it had already induced a moderate degree of lateral curvature. The limb was removed at the shoulder-joint and the patient made a good recovery, being able to get about without pain. The second case was that of a patient aged sixty-four, who, four years ago, underwent the operation of removal of the right breast for scirrhus. Eighteen months ago recurrence occurred, and a large mass formed in the axilla. The arm presented a more marked degree of lymphatic œdema than did that of the last patient; she was obliged to carry the limb in a sling, and it was exceedingly painful. In this case he followed Mr. Treves's plan, dividing the clavicle and amputating the humerus and scapula. The limb, after removal and after much of the fluid had drained away, still weighed fourteen pounds. The wound healed in three weeks and the patient left the hospital much relieved.

Dr. ABERCROMBIE showed a child with a congenital defi-

ciency of a part of the anterior chest-wall. The infant was two months old; there was absence of the third and fourth costal cartilages on the left side and defect of the left second rib. The gap left was protected by nothing but skin; there was also some deformity of the fingers of the left hand. He likewise showed the chest-wall of a child who had been under his care ten years ago with a similar deformity.

Dr. SIDNEY PHILLIPS showed a museum preparation of a somewhat similar case, which, when alive, he had shown at the Society. There was a deficiency of the xiphoid cartilage, and the diaphragm failed to gain an attachment anteriorly, so that the heart's apex lay in the abdomen.

Mr. SPENCER showed a girl who had a sinus in the left loin connected with an abscess in the posterior mediastinum. The collection of pus in the loin formed painlessly, and he opened it and slit up the sinus, finding a narrow channel running in front of the twelfth rib. He cut through the neck of this rib and found that the sinus ran up beside the spine. The examination of it involved great care on account of the proximity of the pleura. The discharge was very profuse and there was a fear of amyloid disease. He contemplated the desirability of extending the search further up by cutting through the necks of the ribs.

Dr. BRISTOW made a communication on a case of sarcoma of the skin which resembled granuloma fungoides. He had unfortunately mislaid his notes, and therefore gave a *résumé* of the case from memory. The patient was aged about twenty-two and had been ill for several months before his admission into St. Thomas's Hospital. He was then emaciated and hectic, and half a square foot of his right axilla, chest-wall and neck were involved in the disease, which progressed rapidly. The skin was covered with projecting nodules which were raised from a quarter to half an inch above the cutaneous surface. They had an appearance very much like erythema nodosum and there were depressions from ulceration. A few of the nodules seemed to die away. On inspecting the ulcers a certain amount of new growth was seen upon their floors. It struck him as being more rapid and more ulcerative than granuloma fungoides. Some of those who saw it considered it to be a case of tuberculosis of the skin, though it was not like lupus. The patient died, and Mr. Shattock pronounced the growths to be sarcoma. But it was a curious point that the lungs were studded with minute tubercles and that the patient had hæmoptysis before his death.—Dr. HADDEN inquired if the lung-growths might not be miliary sarcoma.—Dr. RADCLIFFE CROCKER said that there were two varieties of granuloma fungoides; one in which chronic dermatitis was the first thing, and this was followed by the development of growths, the duration of the case being slow. In the second variety the tumours were formed first, and the case was more rapidly fatal. The French classified these cases under the head of lympho-sarcoma. A case such as those of the second class had been brought by Mr. Swinford Edwards before the Pathological Society.—Dr. PRINGLE inquired as to the method of the spread of the growth at its margin. Sarcoma, in contradistinction to granuloma, usually spread by nodules at the margin; these were at first subcutaneous and only to be discovered by palpation.—Dr. BRISTOW in reply said that the growths did spread by nodules at the margin: these were at first discrete and subcutaneous; some of them disappeared, while others enlarged and joined the main growth.

Mr. ARBUTHNOT LANE related two cases illustrating an operation of complete erosion of the ankle-joint, by which the articulation could be exposed most fully and every particle of its synovial membrane could be seen and removed if necessary. The operation was performed in this manner: A more or less horizontal incision was made from the anterior margin of the internal malleolus, outwards, across the front of the ankle-joint, backwards immediately below the external malleolus, and inwards above the heel to a point over the tendon of the flexor longus hallucis, everything being divided down to the bone. The only structures about the ankle-joint which were not cut through were the internal lateral ligament, the tendons of the tibialis posticus, flexor longus digitorum, and the flexor longus hallucis, the posterior tibial vessels, nerve and the superjacent connective tissue and skin. On adducting the foot any portion of the interior of the ankle-joint was fully exposed, and the narrow prolongation of synovial membrane which ran up between the tibia and fibula could be examined and dissected out by cutting through the inferior interosseous and the anterior inferior tibio-fibular ligaments. It was therefore apparent that the interior of no other joint in the body could be more fully

exposed and cleared of its synovial membrane than could this one by means of the operative procedure suggested. Should the disease have extended to the subastragaloid articulation it was necessary to divide all the structures covering in this joint superiorly and externally together, with the interosseous ligament connecting these bones, and in extensive disease of the astragalus this bone might be excised with advantage. Whether the cut surfaces of the several tendons were sutured together or not seemed to affect the subsequent utility of the foot little if at all. Some care was, however, required in putting the foot up in plaster bandages after the operation that the fibula did not drop back a little off its facet on the astragalus.—Mr. CLUTTON had performed this operation by another method. Seven years ago he did the first case with a good result, and since then he had done six others, only one of which had afterwards to be submitted to amputation. He made an incision on each side from below each malleolus anteriorly; through these cuts he introduced a sharp spoon and his finger and scraped out the joint; cartilage and bone were removed as well if necessary. He subsequently put the limb on a knee-rest and kept it up for one or two years. Mr. Lane's method was evidently good if there was a sequestrum to be removed from the astragalus. In his own cases there had been no trouble as regarded movement of the toes, nor had the bones become displaced.—Mr. GODLEE said that he made lateral incisions and chipped off the malleoli, and thus got a good view of the joint.—Mr. PAGE said that in order to do a thorough erosion it was necessary to get such a view that every part of the joint could be seen; yet he could not help thinking that the cut need not be so free as Mr. Lane had made it, the anterior incision alone from malleolus to malleolus being in his opinion sufficient.—Mr. SILCOCK said that two years ago a case was shown at that Society of erosion of the ankle-joint by an anterior incision, which relieved the patient of the disease and ended in perfect mobility of the joint. After anterior erosion he had seen sensation restored over the dorsum of the foot in a few days, even although the nerve had not been sutured.—Mr. GOULD thought that if the joint could have been satisfactorily dealt with without so extensive a division of tendons it would be better for the patient. He questioned Mr. Lane as to the precise results he had obtained in the cases he had related, more especially as to the mobility of the joint.—Mr. LANE, in reply, said that he had unfortunately lost all trace of the first case. When he last saw him the foot was a good one for walking on, though it was flat and he could not turn the toes up well; there was some mobility in the ankle-joint. The second case had a very good foot. As the child could not move the toes, he had since shortened the tendons. It should be remembered that the cases were so bad that a Syme's amputation was the only alternative, and as opposed to that the results were very good indeed.

## MEDICAL SOCIETY OF LONDON.

### *Intra-thoracic Auscultation:—Surgical Treatment of Cysts of the Vulvo-vaginal or Cowper's Glands.*

An ordinary meeting of this Society was held on Oct. 31st, the President, Mr. Hutchinson, in the chair.

Dr. B. W. RICHARDSON read a paper on Intra-thoracic Auscultation: a New Departure in Physical Diagnosis, which we publish in another column.—The PRESIDENT, after congratulating the author on the excellence of his communication, referred to the possibilities of diagnosis opened up by this new method.—Dr. ROUTH recalled a paper he had read some years ago before the British Medical Association on vaginal auscultation as an aid to the diagnosis of pregnancy &c.—Dr. RICHARDSON, in the course of some remarks in reply, demonstrated the effects of tubes constructed of rubber, metal and cane, his preference being at present for the former.

Mr. ALBAN DORAN read some notes on the Surgical Treatment of Cysts of the Vulvo-vaginal or Cowper's Glands. He began by reading notes of a case in his own practice. The patient was forty-eight years of age, and came to him for relief on account of an unusually large swelling of the left labium, which had existed for several months and caused great trouble whenever she walked or sat down. It fluctuated freely and could be felt extending far into the ischio-rectal fossa. He thought it advisable to remove the entire cyst, the portion in the ischio-rectal fossa being carefully dissected away. Four arteries were divided and required ligature.

The cavity left behind after removal of the cyst was washed out with hot water and packed with absorbent gauze. There was much oozing for five hours, then the wound was dressed again and drained. Within a few days healing was complete. Six months later there was no trace of any fistula. He believed that, as a rule, complete removal of these cysts was the most satisfactory practice. He discussed the question as to whether they arose from Cowper's duct, Cowper's gland, or both. In many cases they arose from the gland, as their deep position proved; but even then, as in his own case, they could be extirpated. Mr. DORAN briefly referred to other forms of labial cyst—"hydrocele," sebaceous cyst, cysts of the labium minus, which were often pedunculated, and the large cyst described by Höning, which extended up into the pelvis, but this variety was of vaginal not labial origin. Most of these forms of labial cyst were curable by partial operations. On the other hand, these proceedings were often unsatisfactory in cases of cyst of Cowper's gland. A sinus, as great a nuisance as the cyst itself, was not rarely left behind. Extirpation cured the disease altogether.—The PRESIDENT said he had not infrequently to deal with these cysts, though it was very exceptional to see them so large or with such a thick wall. The specimen shown was probably of very old standing, and the only treatment at all applicable was excision. In a certain number of the cases he had dealt with he had been content with cutting away a portion of the front of the cyst-wall and applying the actual cautery to the interior. All so treated healed quickly without a sinus. He had generally met with them in a state of inflammation in newly married women.—Mr. SHEILD emphasised the importance of thoroughly checking the hæmorrhage in these cases. Secondary hæmorrhage was especially apt to occur in connexion with operations on the scrotum and labium; the warmth and moisture of the parts, together with slight movement, seemed to favour this. He had treated these cysts by excising a portion of the wall and then applying pure chromic acid to the interior. The acid caused a rapid exfoliation of the cyst wall.—Dr. BRAIDWOOD asked if a microscopic examination had been made of the wall of the cyst.—Mr. DORAN, in reply, said that if it were justifiable to remove the larger cysts, the smaller should *a fortiori* be removed also, for the operation was then a simpler one. The question of sinus was the main point, and the object of the operator should be to obviate the possibility of a fistulous opening remaining after the operation. He had seen many cases in which partial excision had failed. Abscess of these glands he had found to be nearly always venereal in origin, or at any rate to be associated with coitus. It was to be remembered that natural dirt was not septic of itself, though it favoured the growth of cocci. The hæmorrhage was usually easy to control, because it could be kept well in sight. The walls of the cyst were composed of pure white fibrous tissue, with thick walled arterioles.

#### PATHOLOGICAL SOCIETY OF LONDON.

*Traumatic Epithelial Cyst of Hand.—Adenoma of Soft Palate.—Parasitic Cysts from Rabbit.—Acute Traumatic and Respiratory Emphysema of Lung.—Right-sided Ulcerative Endocarditis of Heart.—Atlo-axoid Disease.*

AN ordinary meeting of this Society was held on Nov. 1st, the President, Sir George Humphry, in the chair.

Mr. RAYMOND JOHNSON exhibited a Traumatic Epithelial Cyst removed from the hand of a boy aged ten years. The boy had fallen two years and a half previously, inflicting a small wound on the upper part of the thenar eminence of the left hand. A swelling had slowly formed beneath the scar. This was exposed by a short incision and found to be an oval cyst, pearly white in colour and three-eighths of an inch in diameter. It lay in the subcutaneous fat and was unconnected with the skin. Examined microscopically, there was found to be a complete absence of fibrous tissue from its wall. Externally there was an epithelial covering consisting of several layers of small cells, and within this were laminae of horny epidermis. The contents consisted of epithelial scales and granular débris; there was no cholesterin. It was peculiar that no fibrous wall had formed around it, and the name "epithelial cyst" seemed more applicable to it than "dermoid." The occurrence of dermoid cysts on the fingers in positions not explicable on developmental grounds had been long recognised, and there was sufficient evidence to indicate their

relation to antecedent injury. Reference was made to such cases recorded in the Pathological Transactions—a case under Mr. Poland in which a cyst developed on the finger in the position of an injury from a piece of sharp steel three years previously; a case under Mr. Bowlby in which frequent pricks with a sewing-needle seemed a likely cause; and, lastly, a case reported by Mr. Barker in which the cyst developed in a finger the end of which had been amputated for injury some years previously. Polailon (quoted by Mr. Bland Sutton in his Hunterian lectures) described dermoid cysts of the fingers. He mentioned that they occurred in soldiers and workmen, but gave no definite history of previous injury in the cases recorded. Mr. Sutton had also described specimens in sheep and oxen in which injury seemed a likely cause, more especially in the case of a cyst from the shoulder of an ox. It was easy to understand how a small mass of epithelial cells driven into the subcutaneous tissue would, in the course of their growth, develop into a cyst.—Mr. SUTTON said that in more than one case related the tumour consisted of a tucking in of the whole thickness of the skin. He had examined an implantation cyst from an ox which contained hair and one from a sheep which was filled with wool. Lately he had seen another variety in which the implanted structure had grown as a large wart, only that it was upside down and penetrated far into the deeper tissues. Sometimes, after a punctured wound of the cornea or after a cataract operation, the growth of such a cyst might be witnessed from an epithelial graft accidentally implanted on the iris.—Mr. BARKER said that in the case he had shown there was a very tough fibrous layer externally, then came a layer of ovoid cells and then the horny layers; the cyst was full of cholesterin crystals.—Mr. H. B. ROBINSON referred to a paper by Mr. Stabb in which he described two such cysts, one in the palm of the hand and one in the finger. He himself had removed one from the forehead. There was in that case no history of injury, but it was in structure like those described. The interior of the cyst contained cholesterin.

Mr. CHARLES A. MORTON of Clifton showed a Tumour removed by Mr. Harsant from the Soft Palate of a lady fifty-two years of age. It was noticed accidentally on examination of the throat. It was distinctly encapsuled and easily shelled out. The enucleated growth was round, the size of a walnut, not lobulated, but slightly irregular on the surface, and of homogeneous appearance. It grew, as most palate tumours did, on the left side. Microscopic examination showed it to consist of somewhat large cells, arranged in some areas in irregular branching columns, amongst fine, well-formed connective tissue. In one area there were well-formed gland acini in large numbers, and yet close by the same kind of cells that formed the gland tissue became oval and spindle in form like embryonic connective tissue. This Mr. Morton considered evidence of the embryonic origin of the tumour, and that very early in foetal development, and pointed to the analogy of the structure of the tumour to the complex nature of the ordinary parotid tumour, which was also probably of embryonic origin. He called the tumour "adenoma," simply to classify it with these complex palate tumours, which were all innocent growths, and had been very fully described under that name by Mr. Stephen Paget in St. Bartholomew's Hospital Reports. He wished to call attention to the similarity between the branching columns of cells in this tumour and those described by Mr. Shattock in Sir Wm. MacCormac's case recorded in vol. xxxvii. of the Transactions and Mr. Stephen Paget's in vol. xxxviii. Mr. Morton thought it was not a generally recognised fact that large innocent tumours might develop in the soft palate and at the same time project externally under the angle of the jaw. Out of the thirty-one cases of adenoma of the palate collected by Mr. Stephen Paget, not one projected externally, though two were so large as to be difficult of removal through the mouth. Mr. Dobson of Bristol had described in St. Thomas's Hospital Reports many years ago a fibro-adenoma which was so large that it could hardly be removed between the teeth. This growth (which occurred in a young woman aged twenty-two) developed in the soft palate, and also formed a swelling the size of a chestnut under the angle of the jaw, which, when the tumour was removed from the palate, was found to be part of it. The case had been published as "a case of surgical interest" and had therefore not been noticed by writers on tumours of the palate. Dr. King of Hull brought a similar case before the Medical Society of London in 1871.—Mr. STEPHEN PAGET referred to the complex structure of these growths. They occurred in people either between

fifteen and twenty or between forty and fifty. They grew slowly for years, were usually discovered by accident, and, like the tumours of the parotid, were much more common on the left side. They occasionally gave much trouble from hæmorrhage when they were removed. Not only the adenomatous but the sarcomatous growths of the soft palate could frequently be shelled out from their bed, but this as a rule could not be done when the patients were old or when the growth increased rapidly and in a downward direction.—Mr. SHATTOCK had frequently studied these tumours, but could not make out whether they should be classed with the glandular or the connective-tissue tumours. He thought that on the whole they belonged to the latter group, and many were to be described as "cylindromata," having cells of connective-tissue origin embedded in tissue of a hyaline structure; it was possible that some of them were instances of a mixture of glandular and connective-tissue neoplasms. Such a mixture occurred in common moles.

Mr. H. B. ROBINSON showed the hind-quarters of a tame rabbit. On the inner side of the right thigh and at the back of the left leg there were cysts. There was also a large one below the jaw, and two or three imbedded in the connective tissue of the back. They were of the size of oranges. The cysts had an external bladder, on opening which there were seen groups of bodies like bunches of grapes, containing calcareous granules. They turned out on examination to be scolices of a tenia inverted. The head showed two rows of hooklets, an outer smaller and an inner larger row. They were twenty to twenty-four in number and there were six suckers.—Mr. SHATTOCK said that an object so rare as a tapeworm with six suckers was worthy the attention of a committee, and on the motion of the President the specimen was referred to the Morbid Growths Committee.

Dr. F. C. TURNER showed two specimens of Emphysematous Lesions of the Lung. The first was obtained from a child who died, after being run over, from laceration of the liver, with hæmorrhage into the peritoneal cavity. It showed a fringe of emphysematous vesicles along the inferior border of the lower lobe, which was attributed to opening out of the angle between the chest wall and the diaphragm, by the lateral bulging of the chest compressed antero-posteriorly, and by the simultaneous thrusting down of the liver, crushed between the wheel and spinal column. The second specimen consisted of the lungs of an infant which died with tubercular disease of one kidney and ureter, showing extensive tracts of interstitial emphysema in the anterior parts of the lungs and some scattered emphysematous vesicles over the surface of the upper lobes, in some of which miliary tubercles were visible. The bronchial glands were caseous. The child was marasmic and had suffered from diarrhoea, but not from cough. The extent of the lesions was regarded as evidence of their having been produced by compression of the expanded lung in straining. Some observations were made as to the insufficiency of the expiratory theory to account for an extent of emphysematous lesion capable of greatly interfering with the functional capacity of the lungs, and as to the ultimate dependence of substantive emphysema with barrel-shaped chest on inspiratory expansion associated either with recurrent bronchitis or with some nutritive defect of the pulmonary tissue, diminishing its elasticity and resistance to expansion.

Mr. J. JACKSON CLARKE showed the Heart of a young woman aged twenty-three, who had been under the care of Dr. Broadbent in St. Mary's Hospital. She died of right-sided ulcerative endocarditis. There was an extremely loud bruit, which Dr. Broadbent described as the loudest he had ever heard. There was great stenosis, probably congenital, at the beginning of the infundibulum and consequent hypertrophy of the right auricle. About an inch above the narrowing, which admitted only the tip of the little finger, there were only slight indications of the pulmonary valves, which were all but destroyed by the ulcerative process. The pulmonary artery and its main branches presented extensive ulcerations. Large masses of clot plugged the larger branches of the pulmonary arteries and the lungs contained purulent infarcts. Masses of streptococci were present in the vegetations. Mr. Clarke referred to a similar case which had been under the care of Dr. Maguire.

Mr. CLARKE also showed a Section of the Cervical Vertebra of a girl aged nineteen, who died from atlo-axoid disease. When admitted into St. Mary's Hospital under Mr. Owen the patient was in the gravest possible condition. Mr. Owen found a retro-pharyngeal abscess and at once opened it behind the sterno-mastoid after fixing the head and neck. In spite

of complete drainage, fixation and rest in bed the patient did not improve. Finally Cheyne-Stokes breathing and coma ushered in the end. After death it was found that the abscess had opened spontaneously by a minute pore before it was drained surgically. The atlas was displaced more than half an inch forwards on the axis. The first and second cervical nerves were involved in inflammatory material. The atlas and axis were extensively affected with caries. It was ascertained that the patient had for ten years suffered from occipital pain, which latterly had become most intense.

The following card specimens were shown:—Mr. D'Arcy Power (for Mr. G. N. Stephens): (1) Specimen of Lepra Mutilans; (2) Calculus Encysted in a Child's Bladder.—Dr. E. C. Perry: Secondary Sarcoma of the Small Intestine.—Dr. Ormerod: Stenosis of Pulmonary Valves.—Recent Specimen—Dr. Voelcker: Primary Carcinoma of Pancreas; Thrombosis of left Common Iliac Vein; Embolism of Pulmonary Artery.

## Reviews and Notices of Books.

*A Treatise on Hygiene and Public Health.* Edited by THOMAS STEVENSON, M.D., and SHIRLEY F. MURPHY. Vol. I. London: J. & A. Churchill. 1892.

A COMPREHENSIVE work on hygiene and public health has for some time been much needed by those engaged in the study and practice of this subject. The additions which during recent years have been made to our knowledge of preventive medicine and of the conditions which affect health demand larger treatment than is possible in a handbook. The suggestion made by the late Professor de Chaumont that a treatise should be issued containing essays by various authors was therefore well worthy of adoption, for it is obvious that special knowledge is required for the discussion of each of the several subjects which come within the scope of such a work. In the treatise the first volume of which is before us this course has been followed, and we may congratulate the editors and publishers on their success in obtaining the coöperation of contributors so well qualified to share in its preparation.

A brief but carefully prepared paper on Air is contributed by Professor J. Lane Notter; and it is interesting to observe that the author is, unlike other noted authorities, disposed to assume a causal relation between the air of sewers and diphtheria. This subject is only just touched upon, and then a reference is made to certain investigations by the late Mr. Spear for the Local Government Board. The air of graveyards is credited with the production of cholera and even of scarlet fever; in India, Dr. Notter says, it is well known that cholera assumes a more severe and fatal type in stations where barracks are built in close proximity to the sites of old burial grounds. The evidence as to scarlet fever rests upon an account given four years ago of an outbreak of scarlet fever in the family of a Yorkshire rector whose garden included a part of a disused burial ground, in which had been buried thirty years before a number of persons who had died from this disease. The outbreak in the rector's family followed the disturbance of this ground. Such occurrences undoubtedly deserve careful investigation. They are necessarily rare and are certain, in the first instance, to be received with some incredulity, and the adoption of this theory by Dr. Notter will no doubt lead to closer inquiry into the question whether the air of graveyards can, under these exceptional circumstances, be productive of disease.

Dr. Notter's paper is followed by an admirable article on Warming and Ventilation by Mr. W. M. Shaw. This is perhaps one of the most valuable contributions to the work, for the author has in little more than a hundred pages given a clear and comprehensive account of this subject. After discussing the physical properties of air and devoting two sections to water in the air and dust and smoke, Mr. Shaw

considers in detail the principles of ventilation, dividing the process into general circulation and local circulation and discussing the effect of different characteristic conditions, finally applying these principles to special cases. A valuable account is given of the various ways of producing heat and the economy of production, and, later, of the method of carrying heat from one central furnace to rooms more or less distant from the furnace. The whole subject is treated in a thoroughly scientific manner and the argument is illustrated by numerous formulae.

Mr. Shaw's article on Ventilation is followed by papers on Meteorology and Climate; the former by Mr. G. H. Symons, F.R.S., and the latter by Dr. Theodore Williams. Mr. Symons' contribution is practically a concise account of meteorological conditions and instruments; while Dr. Williams discusses the influence of these conditions on health, and gives in brief form an excellent account of different climates which will be not less useful to the practitioner than to the health officer. Water is treated by one of the editors (Dr. Thomas Stevenson), who gives in some eighty pages a good summary of the subject. Considering the question of the self-purification of rivers, the author fully recognises the changes which are effected in running waters; but he writes cautiously as to the distance which is required to render fit for domestic purposes the water of a river which is excrementally polluted, and he states that "observation appears to show that a flow of twenty miles in a river is not sufficient to destroy the germs of typhoid fever." The section on Lead Pollution will be read with much interest. Dr. Stevenson states definitely that neither the silica theory nor the acid theory of the action of water on lead accounts for the whole facts known.

Dr. Copeman's article on Soil is a laborious piece of work, giving evidence of careful study of the vast amount of literature of this subject which is now available. The author has had full regard for bacteriological considerations in its treatment. Referring to the question of lead pollution, Dr. Copeman evidently attaches greater weight than Dr. Stevenson is disposed to do to the theory that the ability of some waters to dissolve lead is due to bacterial life, and he cites the memorandum by Mr. W. H. Power contained in the report of the medical officer of the Local Government Board for 1887. The paper will prove extremely useful to those who have not access to the works of foreign writers, especially of those of the Germans, by whom the question of soil has been especially studied.

Food has been treated by Dr. Sidney Martin in an article which contains a valuable account of dietaries and food-stuffs, and which will serve well as a trustworthy source of reference. This article is followed by a short paper on Meat Inspection, by Dr. E. W. Hope, who later in the book contributes an article on Slaughter-houses, both of which are evidently based upon much personal experience. Clothing is discussed by Dr. G. V. Poore in a practical article, in which account is given of the materials used for clothing as well as of the articles of clothing employed for different parts of the body. Physical Education is treated in considerable detail and with much common sense by Mr. Frederick Treves, who, after discussing the effects of exercise, deals in a practical manner with each of the more common sports. As a guide to the management of the exercise of children and young adults this article deserves the study of all. The article on Baths, by Dr. Hale White, includes an account of the different kinds of baths and their physiological action.

An admirable paper on the Dwelling is from the pens of Messrs. Gordon Smith and Keith Young. In this article are discussed the house usually occupied by a single family, houses occupied by more than one family, prisons, barracks, schools, general and special hospitals, including those for cases of infectious disease. This article gives excellent

advice as to the arrangement of public institutions and is freely illustrated with plans showing the different systems which have been adopted. It is followed by a paper on "Hospital Hygiene" by Mr. H. G. Howse, who in dealing with the management of such institutions shows the results which have been attained by antiseptic treatment.

The Disposal of Refuse is treated by Professor Corfield and Dr. Louis Parkes in a carefully written article which includes a full discussion of different methods of conservancy and of the treatment of sewage. Offensive and Noxious Businesses is from the pen of Dr. T. Whiteside Hime, who includes in his paper an account of the various trade processes causing effluvia, nuisance, or in connexion with which there may be chemical poisoning, together with the means which should be adopted for the prevention of nuisance or injury. It is impossible in the space at our disposal to discuss in detail the work of the several authors who have contributed to this volume, but we may briefly say that the publishers have been fortunate in securing editors of such acknowledged ability and standing, that the editors are to be congratulated on their choice of contributors, and that the work has been well done. If the next volume is compiled with the same care and completeness which characterise the first one, the want of a comprehensive book of reference on public health will have been admirably met. The work ought to have a wide circulation, not only in England, but wherever the English language is spoken; and it is likely to become an essential book of reference with all who undertake any duties which involve considerations of health.

*Swin, Swale and Swatchway; or Cruises down the Thames, the Medway and the Essex Rivers.* By H. LEWIS JONES, M.A.; assisted by C. B. LOCKWOOD. London: Waterlow and Sons, Limited. 1892.

THE estuaries of the Thames and Medway, with their infinite complexity of sands, channels, rivers, buoys and lights, afford to the fortunate few a health-resort of unrivalled interest and value. After a hard week's mental toil to run away from London and arrive in an hour or two at Port Victoria, Queenborough, Leigh or Southend, and to find there the trusty three-ton yacht which the holiday-maker and his partner have known so long and can manage so well, revivifies the most-jaded intellect. Running out of the small and secluded port where his ship has been lying, with simple but sufficient stores, he embarks on cruises which may be almost indefinitely varied, and any one of which may be completed in a day or two. Frequent hard work, occasional discomfort and even anxiety attend upon the enterprise; but these form a great part of the charm and are amply compensated by the placid sea and river views, the sunrises and sunsets, and the simple meals which go with them. This little book, smartly written and illustrated not only by photographs, but also by interesting antiquarian and historical comments, will be incomprehensible to the many, but keenly interesting to the few. With the latter class the minute accuracy of the topographical details, the sea-wisdom of the directions for guidance in all but unknown creeks and channels, are simply fascinating. That anyone who has tried small yacht-sailing in out-of-the-way corners and has learned its many charms, its freedom and its exceeding cheapness should prefer a "Saturday to Monday" at the seaside seems remarkable. Of course, small yacht sailing requires skill and much experience, and unless one at any rate of the partners possesses these qualifications a paid hand is essential. But those who wish to learn to sail should reserve the paid hand for emergencies and, subject to his criticism, should do all the work for themselves. Steering from the Thames into Hole Haven above Canvey Island after dark and anchoring not too

near the powder magazine or the steep mud-banks is a very good exercise, and in case of the worst there is an inn close by.

*The Physiology of the Invertebrata.* By A. B. GRIFFITHS, Ph.D., F.R.S. Edin. Pp. 477. London: L. Reeve and Co. 1892.

THE title of "Anatomy and Physiology of the Invertebrata" would be more appropriate than that which Dr. Griffiths has given to his treatise, for many paragraphs are as much anatomical as physiological. It is indeed questionable whether anyone is competent to write a book devoted exclusively to the physiology of the lower animals—so much is conjectural in regard to the functions of the various organs, so little is positively known. Even in the case of such a characteristic organ as the eye of insects Dr. Griffiths writes: "The sense of sight must be keen in the insecta, but their mode of vision is essentially different from that of the higher vertebrata," and he quotes, apparently with approval, Professor C. Lloyd Morgan, who remarks: "Remember their compound eyes, with mosaic vision, coarser by far than our natural vision, and their ocelli of problematical value and the complete absence of muscular adjustments in either the one or the other. Can we conceive that, with organs so different, anything like a similar perceptual world can be elaborated in the insect mind? I for one cannot." If this holds good of the eyes of insects, what can be said of many other organs whose functions are far more obscure? The method adopted by Dr. Griffiths is to devote successive chapters to the several functions. Thus the functions of digestion, absorption, the blood, circulation, respiration, secretion and excretion, nervous system, organs of special sense, movements and locomotion, and reproduction have each a separate chapter in which the special function is fairly discussed. The imperfection of our knowledge renders the account given under these heads, however, rather disjointed and fragmentary, and very soon tires the reader. It is, in fact, a book of reference. At the same time it must be admitted that Dr. Griffiths, besides giving the result of his work in many cases as an original investigator, has spared no pains to make himself thoroughly familiar with all recent researches. In the chapter on Respiration, for example, he gives a very full account of the colouring matters of the blood in the invertebrata, together with the relation of these pigments to the respiratory function. This account contains references to the observations of Mr. MacMunn, Professors Geddes, Lankester, Bunge and others, and there is much under this head that cannot be found in the ordinary text-books. The relations of many insects to carbon dioxide are remarkable. The author states that he found that some can resist the action of an atmosphere containing from 40 to 70 per cent. of carbon dioxide, which may perhaps account for their early appearance in the history of the earth, when the atmosphere was probably more highly charged with this gas than at the present time. Dr. Griffiths kept a stag beetle alive for six days in an atmosphere containing 60 per cent. of chlorine, which to the lungs of higher animals is a very poisonous and irritating gas. Mr. MacMunn's investigations on animal pigments obtain an amount of recognition that must be extremely satisfactory to him, for on casually opening the volume we were struck with the circumstance that Mr. MacMunn's name appears sometimes two or three times in eighteen pages successively—not that we at all undervalue that gentleman's researches, but in truth they constitute rather dry reading. A good description is given of the green glands of the decapod crustacea, the functions of which Dr. Griffiths' own researches have done so much to elucidate. The curious idea was at one time held that these glands were the auditory organs. The conclusion at which he has arrived is that they are urinary organs; the secretion containing uric acid and

traces of guanin. In connexion with this he gives an important table, also compiled from his own investigations, showing the different modes in which the kidney is represented in the several groups of the invertebrata.

Some errors occur in the account of the determination of the rapidity with which motor nervous excitation is transmitted in the lobster. The whole paragraph requires to be rewritten to render it intelligible. A few typographical errors also occur, as, for example (p. 306), "polyprite" for "polypite" and (p. 218) "cornynactis" for "corynactis"; p. 217, "sagarita" for "sagartia"; p. 67, "unis" for "unio"; p. 444, "Grundzünge" instead of "Grundzüge"; but, on the whole, the editing is well done. The treatise will prove useful to those who are students of comparative physiology and is the only one we possess in the English language.

The author states his indebtedness for some of the illustrations to his sister, Miss M. Griffiths, and they reflect credit on her skill.

## Analytical Records

FROM

### THE LANCET LABORATORY.

#### BRAVAIS WINE AND BRAVAIS ELIXIR.

(NOBLET AND CO., THE BRAVAIS WINE COMPANY, 5, AVENUE DE L'OPÉRA, PARIS.)

THE preparation of this wine was suggested by M. Bravais, the analytical chemist to whom we owe the original formula for the preparation of dialysed iron. It contains the tannates of cocaine, caffeine and theobromine, which embody the active principles respectively of the coca plant, the kola nut, and the interesting Brazilian shrub, *Paullinia sorbilis* or Brazilian cocoa. As affording an excellent vehicle for these principles a superior sherry (Pedro Zimenes) has been employed. The genuine character of the wine is made evident by the following results of an analysis which we have recently made. On evaporating the wine to dryness, and extracting with ether after the addition of sodium carbonate, the ether yields a crystalline residue, which produces numbness on the tip of the tongue, and which, with hydrochloric acid, forms characteristic crystals of cocaine hydrochlorate. If the residue, after extracting the cocaine, is then treated with chloroform, beautiful silky needles of caffeine, identical also with guaranine, are obtained. The presence of tannin is sufficiently indicated by the perchloride of iron test. In addition, to these results the following were obtained: Alcohol, by weight, 12.69 per cent.; by volume, 15.68 per cent.; residue, consisting of sugar and the active principles alluded to, 16.29 per cent.; mineral matter, 0.37 per cent. The wine resembles a dark sherry, is generous to the taste and doubtless possesses properties of distinct therapeutic value referable to the tonic and invigorating principles the presence of which our analysis has confirmed.

The composition of the elixir is founded on similar lines. It is practically a rich curaçoa containing caffeine and cocaine. The presence of tannin and cocaine, however, was not clearly indicated. Analysis furnished the following data: Sugar and extractives, 39.33 per cent.; mineral matter, .017 per cent.; alcohol, by weight, 32.69 per cent.; by volume, 39.25 per cent. On dilution with water the elixir becomes opaque owing to the separation of essential oils, but the opacity vanishes at once on the addition of ether. It is a pleasant liqueur, and its value is of course enhanced by virtue of the stimulating and restorative ingredients present.

#### EXTRA QUALITY ÉPERNAY.

(PERIGUEUX ET CIE., ÉPERNAY.)

An excellent sample of the 1889 vintage from the famous Épernay district. It is an agreeably dry wine, of fruity

character, yielding 3.53 per cent. extractives and 0.12 mineral salts. On distillation 100 volumes afford 12.77 volumes of alcohol, equal to 10.31 per cent. by weight, or in terms of proof spirit 22.38. The ash contained a distinct quantity of iron. The wine is evidently of sound quality and none the less satisfactory because it is entirely free from added preservatives and from metallic contamination.

#### SPECIAL GLEN URQUHART HIGHLAND WHISKY.

(HENRY URQUHART, LONDON.)

There is no doubt that whisky is all the more wholesome for being stored in wood for a few years. The reason that whisky mellows in wood and not in the slightest degree in bottle appears to depend upon the selective power of the wood to absorb and retain the higher alcohols of which amylic or fusel oil is a type. Glen Urquhart is described as an old blended spirit, and judging from the character and smoothness of its flavour it is properly so described. It contains only 0.11 per cent. extractives and merely a trace of mineral matter. The alcoholic strength is somewhat below the average, as may be seen from the following figures: Alcohol, by weight, 40.30 per cent.; by volume, 47.67 per cent., or 83.54 proof spirit. In terms of proof spirit, in fact, it is only eight degrees above the limit of strength fixed by the Excise.

#### TABLOIDS OF COMPRESSED ERGOTIN.—THE "ÉLITE" TOILET LANOLINE CREAM.

(BURROUGHS, WELLCOME & Co., SNOW-HILL BUILDINGS, E.C.)

The active principles of ergot are not definitely known, although an alkaloid which appears to be identical with Wenzel's ergotinine has been separated. Ecboiline has also been obtained by Wenzel, but a research by Dragendorff tends to show that both Wenzel's ergotinine and ecboiline are inactive. From ergot have also been obtained scleromucin, sclerotic acid and as inert principles a red colouring matter scleriodin and two crystalline substances, which are without physiological action. The above tabloids are sugar-coated and contain a glistening brown mass which, when extracted with alcohol and acidified with sulphuric acid, gives a brownish-red solution absorbing the green and a large section of the blue rays in the spectrum. This useful administrative form is calculated to give the drug additional value and probably more extended application. Each tabloid is stated to contain three grains of Bonjean's extract.

Lanoline cream is intended for toilet purposes, for which, in fact, no other unguent is better fitted. It is readily absorbed and has no tendency to become rancid, a property which seems to be concomitant with its refractory behaviour towards alkalies; it does not saponify readily. The "élite" cream is evidently worked up or emulsified with water delicately scented with rose extract: on heating, water is given off, accompanied by a fragrant smell, while perfectly pure and transparent lanoline oil remains.

#### MIST. BISMUTHI OXYCHLOR. C. PEPSINA.

(A. G. DRUCE, 3, MELVILLE-TERRACE, EDINBURGH.)

The main novelty in this preparation lies in the fact that the oxychloride of bismuth is used in its composition in preference to the subnitrate or other salts. This is in all probability a useful departure and doubtless adds to the remedial action of bismuth. The preparation also contains pepsin, the activity of which we have ascertained by experiment. The oxychloride occurs as a very fine powder in suspension in a syrupy fluid, which on examination proves to be glycerine. The salt separates, however, on prolonged standing, but a little shaking suffices to give a uniform mixture again. We do not know what the action of oxychloride of bismuth upon glycerine may be—if perchance there is any at all,—but we noticed a distinct pressure in the bottle, accompanied by slight effervescence, on withdrawing the cork.

#### SUPERFATTED BORIC ACID SOAP.

(R. SUMMER & Co., LIVERPOOL.)

This well-made soap is free from excess of moisture and alkali and contains a suitable proportion of boric acid. It is accordingly endowed with properties of some antiseptic value. The test for boric acid was satisfactory.

#### SANTAS CREAM.

(THE SANTAS CO., LTD., BETHNAL-GREEN, E.)

This preparation consists of an ointment strongly impregnated with a soluble variety of sanitas oil. It has a pleasing and persistent odour of sanitas and dissolves entirely in water forming a soapy solution. An oil separates from the solution on addition of acid, and the clear liquid on evaporation yields a sodium salt. The preparation may therefore be regarded as a soft sanitas soap possessing distinct antiseptic and oxidising powers, and therefore available for use with certain advantages for dressing burns and other wounds, or as a cleansing and effective mouthwash.

#### HOVIS BREAD AND BISCUITS.

(S. FITTON AND SON, FLOUR MILLS, MACCLESFIELD.)

Evidence is forthcoming almost every day that the old and faulty system of preparing bread hitherto exclusively adopted, which consisted in producing a perfectly white loaf at the expense of some of the most valuable constituents, will soon be entirely superseded by the more scientific method by which the maximum amount of nourishing material of the cereal both organic and inorganic is secured. Our examination of the samples enumerated above, which are skillfully prepared on the lines indicated, proved entirely satisfactory. Hovis bread is made from flour stated to contain 2 per cent. whole meal and 25 per cent. of germ flour. Germ flour itself contains no less than a third of its weight of nitrogenous matter, 2.57 per cent. phosphates, 15.62 per cent. fatty matters, 1.72 per cent. fibre, and a third of its weight of starch. Its composition signifies, in fact, a concentration of the nourishing elements of wheaten flour into a third of its bulk, to the exclusion of more than half of the starch. As affording a check on these figures, we have submitted the sample of bread to careful analysis and find that its composition may be thus represented: Moisture, 49.41 per cent.; mineral matter, 1.25 per cent. (containing an abundance of soluble phosphates); starchy matters and fat, 39.04; nitrogen, 1.63 per cent., equal to albuminoids, 10.30 per cent. According to this its food value, both as regards nitrogen and phosphates, is, broadly speaking, double that of bread made with ordinary wheaten flour. Under the microscope the structure presented is that of well-cooked bread of uniform texture containing a due proportion of fibre, which, it is important to add, consists of fine and not coarse particles. Not less satisfactory is its property of keeping moist, and therefore palatable, for several days. The biscuits are made of the same flour; they are attractive in appearance, crisp and of excellent flavour. It will be conceded that a system which produces impoverished food is to be deprecated, while a system which tends to secure rather the enrichment of food is strongly to be commended. The system under notice meets with our entire approval.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.—A meeting attended by many of the leading members of the medical profession of Derbyshire was held at the Royal Infirmary, Derby, on Oct. 21st, for the purpose of forming a division of this Society for Derbyshire and adjacent parts. Dr. Greaves of Derby, who occupied the chair, spoke in favour of forming such a division for Derby, and stated that from facts within his knowledge there was a necessity for combining for the purpose of protection against unjust attacks and other evils to which members of the medical profession were especially liable. It was eventually unanimously resolved to form a Derbyshire division, and the following officers were appointed:—President: Dr. C. Greaves. Vice-Presidents: Dr. Curgiven, Mr. T. Johnston (Belper) and Mr. Symes. Secretary: Dr. C. H. Taylor.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 5, 1892.

WE would direct the attention of our readers who are interested in the establishment of a Teaching University in London to the able and judicious article which we publish on page 1062. There can be no doubt, as Professor ERICHSEN so clearly shows, that the opportunities for clinical instruction that exist in this metropolis are unrivalled either in Europe or in the United States of America. But these opportunities are arranged without any regard to the requirements of the medical student. In many centres of medical instruction we find some such system as the following—viz., one large hospital which possesses an enormous number of beds and around which the scientific laboratories &c. are congregated, every aspect of medical teaching being thus focussed. In London we have a system which is the direct opposite. Eleven teaching hospitals have 4542 beds divided amongst them, whilst twenty-seven Poor-law infirmaries in the metropolitan area contain an aggregate of 13,825 beds. We need not refer to the general hospitals which have no schools attached to them, or to the special hospitals, or to the enormous mass of out-patients who are daily seen at the various London hospitals. We would only incidentally point out that during the last month more than 4000 patients were under treatment in the metropolitan area in the fever hospitals alone. The immense amount of material for clinical teaching afforded in the metropolis has never perhaps been so forcibly put forward as by Professor ERICHSEN, and we commend the consideration of it to the Royal Commission. The obvious deduction is that these opportunities should be fully utilised. It is notorious that at the present time this is not the case. A student at a London medical school in the course of his career there can, however diligent, learn no more than is placed before him by his teachers at that school. He is practically debarred from acquiring a knowledge of any other advances in science and new procedures in diagnosis and treatment which he might meet with elsewhere. We need not urge how important it is for future practitioners to be *au courant* with the progress of medical science and with its bearing on the treatment of disease in its multifarious forms. But in London, with its large number of medical students, one centralised institution for the teaching of the sciences ancillary to medicine would be most disadvantageous. There is ample room, and there would be a sufficient number of students for at least three or four fully equipped scientific schools and their necessary laboratories, and this would secure due competition among the teachers. For post-graduate clinical teaching the case is somewhat different, and all the material in the metropolis and the services of every individual teacher should be available in the case of each student of medicine. The practical question is—How can the medical student who obtains his education in this unrivalled centre gain the greatest advantage from these opportunities? To this query Professor ERICHSEN has

given a complete answer. Whilst *in statu pupillari* the student should follow the teaching of his professors and lecturers at the medical school to which he is attached. At this period of his career he will probably gain nothing by endeavouring to follow the teachings of any other lecturer, however distinguished, at another medical school. If he attempts to avail himself of the instruction of the various surgeons and physicians who may have attained a reputation through professional eminence or by reason of strong individuality as teachers at various schools, he will probably only waste his energies without having obtained any definite reward in the shape of exact knowledge. But if, after he has passed the examinations necessary for a diploma, he were able to attend for a year or two upon properly selected courses of special teachers he would learn much, and the knowledge thus acquired would be to him an immense boon in his later career. To secure these advantages Professor ERICHSEN has made a most important practical suggestion. Every hospital and medical school should, he suggests, be federated, and then, instead of the present system of scattered post-graduate courses, the various institutions in the metropolis would be available for post-graduate teaching. But this result can only be obtained by the federation of all the institutions under the guidance of a local university.

The University of London has entirely failed to bring together the medical resources of the metropolis for such a purpose. It has contented itself with a mere examination standard, and has done nothing towards collating the educational advantages which London possesses in the matter of the teaching of medicine, surgery and the collateral sciences, and we fail to see how, under any *régime* like the present, such advantages can be properly utilised. A purely examining board can do nothing towards the attainment of this most desirable end. It is very doubtful if any reconstitution of the University can enable it (whilst carrying out at the same time its special function as an examining board for the empire) to perform this duty, which ought to be one of the greatest functions of a local University for London. For these reasons, amongst others, we hope that the Royal Commission may see its way to recommend the formation of a local university, and such federation would then be one of the first matters to secure attention. Incidentally we would remark that in Professor ERICHSEN'S article one statement has been made under a mistaken impression. Two years of residence are stated to be a necessary requirement for all candidates for a full degree at the Scottish universities, as well as at the teaching universities of England. There is one exception to this—viz., that at the University of Durham an attendance for one year on the lectures and hospital practice at the Medical School at Newcastle-on-Tyne is all that is at present required for the medical degrees of the University of Durham.

THIRTY-TWO years' missionary work in the highlands of Ethiopia entitled its hero, Cardinal MASSAIA, to all the honours that attended his declining years and also to the beautiful monument just unveiled to his memory, with every accompaniment of admiration and respect, in the Capuchin Church at Frascati, on the Alban Hills. These outward

tributes are but a feeble expression of the gratitude owed to him by humanity. Alone and single-handed, half a century ago, he dared to penetrate into regions where European foot had seldom or never trod, and though his errand was the diffusion of the light of Christianity, his mode of carrying it out was as signally and fearlessly his own as the routes he opened up and the weapons he fashioned as well as found. GULIELMO MASSAIA was no common missionary, proceeding on well-worn lines and using traditional methods. He had a profound knowledge of his fellow man in every grade of civilisation, and in his dealings with him he brought that knowledge to bear through every possible channel. He taught the benighted Shoans and Gallas what was meant by civilisation, and proved to them that the shortest cut to it was Christianity. He took care of their bodies as the first step to enlightening their minds. He made a special study of the climatic and health conditions under which they lived and moved, and accurately observed the diseases which they generally inherited. When an epidemic prevailed he studied its origin, its course, its issue, the circumstances that encouraged or checked it and the remedies to which it yielded. He inspired respect among his savage congregations by his fearlessness and confidence amid shafts that "fly in darkness," and won them to his gospel teaching by the personality he typified and the example he gave. In the dominions of the Shoan King MENELIK he faced and subdued a formidable outbreak of small-pox, and he prevented its return by rigorous and systematic vaccination. Although without professional qualification he had yet acquired a knowledge of science, and this he used on every possible occasion with intelligence, energy and effect.

It is gratifying to see that the methods of MASSAIA are receiving increased attention on the part of those engaged in mission work, and that, irrespective of religious differences, the societies of the several Protestant churches are not averse to profit by the example of that of the parent from which they are detached. In one direction they might take yet other leaves from the Roman Catholic book. Before us lies a publication issued under the approval of the Vatican and circulated widely among the priesthood—among all those, in fact, who, abroad as well as at home, are brought into daily contact with their fellow man in all the occurrences and crises of domestic life. It is the "Medicina Pastoralis" of Dr. CAPELLMANN, a work which has reached nine editions in its German original, and three editions in the Latin dress it has assumed for those to whom German is an unknown tongue. It supplies, from the pen of a thoroughly qualified practitioner, the information which an intelligent ecclesiastic might be trusted to apply in the absence of the regular medical man. Cautiously compiled, it addresses itself to those who, as members of a liberal profession, have been taught "to know what knowledge of a subject means," and who will therefore use its advice and its prescriptions with the circumspection and under the safeguards which the half-educated sciolist or amateur so invariably despises. It is, in short, an illustration of what has long been an honourable tradition of the Church of Rome—that of maintaining a respectful and loyal attitude towards the profession of medicine, and at the same time supplying to those of its priesthood who are brought into relation, whether

as pastors or as missionaries, with flocks unfavourably circumstanced, a carefully arranged set of rules and prescriptions. Thus equipped it is not difficult to understand how, in past times, the Jesuit missionaries became active instruments in diffusing in unexplored countries their knowledge of diseases and of remedies. Hand in hand with their spiritual teaching they bore the light of medical knowledge into uncivilised regions, and repaid the profession, on whose armoury they drew, by bringing back to it descriptions of maladies and their treatment, of drugs and their efficacy, of poisons and their antidotes, which have laid scientific medicine under obligations to them for all time. The opportunities of the medical missionary are great, often unique, and it is to increase the effectiveness with which these may be utilised that we think the attention of the various societies might be directed.

That their work is in need of every adjunct to its efficacy is on all sides admitted, and competition between them cannot fail to have its usual wholesome results. Let it be realised in its full breadth and depth how essential it is that religious inculcation should go side by side with physical health or rehabilitation and the medical arm of missionary enterprise will be as jealously trained and equipped as the spiritual. Public opinion is rapidly ripening to a recognition of this interdependence of the two professions, and its material or moral support will be the more liberally and efficaciously bestowed as it sees that they work both at their full strength and both in harmony. The multiplication of such institutions for medico-missionary training as that which has so long and so successfully been in operation at Edinburgh will be a next step to the closer and more effective alliance of the two callings, and we shall every year be more and more spared the not very reassuring spectacle of relays of missionaries being sent out at great expense and with high expectation to benighted regions and not a medically qualified man among them to supplement and sustain their efforts. The other day, as a result of the "forward movement" taken fifteen months ago by the directors of the London Missionary Society, nearly forty missionaries were added to their foreign staff. Of these, twenty-six bade farewell on Wednesday, the 26th ult., to their friends in Exeter Hall before leaving for their posts, and nothing could have been more touching or more impressive than the ceremony. Well-wishers to the cause, however, must have missed among the nobly inspired band, male and female, the due proportion of those medically qualified; and though medicine was by no means unrepresented among them, still the addition of many more thus equipped would have inspired a better grounded anticipation of success. Quite apart from the spiritual interests of the communities among whom the missionary labours—all-essential as these interests are—the political interests also at stake are not to be overlooked. As Sir CHARLES AITCHISON recently showed, we are indebted to our hold on our great Indian dependency more to missionary effort than to any other cause, and a master-force in that effort has been the medical contribution. In newly acquired regions, indeed, where we have to encounter a competition unknown to us in India, the reinforcement of our influence and the consolidation of our control is to be effected by every means available. These are not the times nor are those the regions where we

can afford to underman our expeditionary enterprise or to leave its equipment defective at any point. The missionary work is one of the most powerful weapons at our command, and in that work the medical element is not the least efficacious. It will be our own fault if, recognising these facts, we allow ourselves to be outstripped by foreign competitors who derive from the church of their fathers a traditional skill in pressing every missionary qualification into their service, the medico-missionary included.

Young men in their conflict with temptation to sexual vice often suffer under the disadvantage of receiving but little help from those to whom they ought to look for it with confidence. Few parents have the knowledge and the wisdom to tell their sons the most important truths about the sexual passion just at the time when it is becoming developed in them, and the latter are therefore left an easy prey to their strange desires and to those "lewd fellows of the baser sort" who are always at hand to corrupt innocent youth. If it is true that to a very large extent parents are unmindful of one of their gravest responsibilities, it is no less true that the medical profession has often failed in its duty in connexion with this subject. Medical writers and medical men generally are too often silent on this matter, and, unfortunately, when the silence has been broken it has not always been with words of truth and soberness. We are constantly hearing and saying that "knowledge is power." Yet we find that little effort is made to impart the knowledge which would largely aid in preserving the virtue of the young, and the most pernicious teaching of those who, for the lowest of reasons, propagate error is left unnoticed. Knowledge alone will never make a people virtuous, but it is an invaluable aid to those who are striving to control their passions. Seeing on all sides the terrible physical, mental and social havoc wrought by sexual vice we feel that the medical profession should do its utmost to stem the evil, and, at any rate, should give utterance to the truth with no uncertain sound. What are the physiological facts that ought to be proclaimed by the medical profession? Mainly these. In the first place, that occasional involuntary emissions of semen during sleep, and often in association with libidinous dreams, are natural occurrences in unmarried continent men, and are neither the cause nor the consequence of disease. The emissions are most frequent between the ages of eighteen and twenty-five; they vary in frequency in different men, but are favoured by sedentary occupations and by lewd thoughts. The subjects of these emissions sometimes complain of various sensations of malaise, which they attribute to the depressing influence of these losses; but it is a striking fact that such symptoms are only met with in those who have an exaggerated or erroneous conception of the significance of the discharge, and that they quickly disappear when their real meaning and causation are understood. To regard such a physiological occurrence as a disease and name it "spermatorrhoea" is a very serious error.

The second fact we wish to insist upon is that sexual continence does not beget impotence, and that the all-prevailing cause of impotence is prolonged sexual excess. In support of the opposite conclusion appeal has been made to analogy. It has been pointed out that unused muscles and

bones waste, and therefore, it is urged, it must be true that continence will lead to impotence. Such argument is utterly fallacious, as are most arguments from analogy. Facts in abundance prove the contrary. Common as is sexual vice, continence is not unknown among us, and the truth of our statement is not difficult to verify. The real argument from analogy is drawn from the breast. This gland is generally inactive for many years after puberty, and yet, whenever the call for its activity arrives, it is more or less perfectly responded to. As a matter of fact impotence does not depend upon the testicle, but upon the spinal cord; the sexual act is a physiological nerve storm, and not simply an act of secretion. Loss of sexual potency is due to some fault in the nerves of the parts, or more commonly in the centre in the spinal cord, which presides over this function. It is often a solitary nervous phenomenon, and by itself is not of grave import.

The third physiological fact we ought to teach is that no function of the body is so influenced and controlled by the higher nerve centres as the sexual. It is excited by lewd imaginings, loose talk and sensuous scenes. It is set in motion by even accidental stimulus of any part of the nervous system affected by the sexual orgasm. Hence the difficulty of continence. On all sides are sights and sounds that may become the stimulus of sexual excitement. The other side of the picture is equally true. By the exercise of watchfulness and self-control the occasions of such excitement may be reduced to a minimum and the passion may be subdued. Medical men are sometimes asked to formulate rules of diet and exercise—hygienic rules—by which immorality is to be banished. The task is altogether impracticable. Vice is voluntary, and it is only by the exercise of a resolute self-will that virtue is maintained.

We cannot but believe that were these three very elementary but fundamental physiological truths properly presented and enforced upon young men very much misery would be avoided. Ignorance of them drives men into the clutches of ruthless charlatans, leaves them a prey to groundless fears, and often leads them into vicious habits from which they are unable to free themselves. To withhold such knowledge is in many cases to leave youths in ignorance of the one power by which they can successfully contend against the evil. We feel strongly the urgent importance of this matter, and hence we speak plainly and hope that others, as they have opportunity, will do their best to help young men in their struggle against vice.

SIR HENRY THOMPSON'S letter to *The Times* has again drawn attention to a question of vital interest to the medical profession and the community at large. More than one recent case has served to point to defects in our system of death certification and registration. The most notorious was that of MATILDA CLOVER, whom NEILL poisoned with strychnine. It will be remembered that CLOVER'S death was registered and her body buried in the usual way on the strength of a certificate given by a medical man who had previously to her last illness been her professional adviser. It has been remarked that the miscarriage of justice, if it may be so termed, was due not to any inherent defect in the existing system of registration, but to a violation of the

duty imposed upon medical men in the matter of signing death certificates. Probably, but not certainly, an inquest would have been held in CLOVER'S case had a certificate not been forthcoming. We say probably because only one of two other events might have happened—either the coroner, on a report made to him, might have deemed the reasons for holding an inquest insufficient, or, failing a medical or coroner's certificate, the registrar might have recorded the death and issued an order for burial.

Against the possibility of registration under such circumstances it is clear that the strictest provisions should be made, and obviously the decision in any doubtful case ought only to rest with some person or persons well qualified to discharge such an important duty. A misrepresentation wilfully or carelessly made by a medical man might of course be undetected; but cannot we hope for a greater safeguard than at present obtains—namely, the fact that false certification is a punishable offence? We think so. If the registration of deaths was committed to the care of some specially qualified person, such official might be supplied with formulæ for interrogation, the use of which would enable him to detect an attempt to deceive or correct an error from inadvertence or carelessness. No doubt this would entail considerable additional expenditure, but it is a question whether the present complicated system of "civilisation," especially in our large towns, is not at once a demand and a justification for creating a system to obviate some of its attendant evils. Of this much we are certain, that registration of death should be prohibited until an inquest, or at least a post-mortem examination, has been made in every case where there is the merest suspicion of foul play or absence of all direct evidence of the demise. The increasing popularity of cremation carries with it the necessity that every possible precaution should be taken against the destruction of evidence which might lead to the detection of crime in particular and act as a deterrent to its commission in general.

## Annotations.

"Ne quid nimis."

### CHOLERA AND DESTITUTE ALIENS.

WE are again face to face with an immigration of aliens which is associated with danger to public health. Certain shipping companies have renewed the traffic of destitute Russian Jews between Hamburg and the port of London, and certain individuals at the East-end are doing what they can to induce the aliens to settle down in London and are supplying the immigrants with addresses to which they can say that they are going. Over one hundred aliens from Hamburg have thus entered London within the past fortnight, and inquiry as to their whereabouts after they have landed has shown that, as regards a substantial proportion of them, the addresses given were incorrect. Our system of cholera prevention is based on the assumption that sanitary authorities shall be informed by the port authorities of the localities to which persons arriving, either in infected ships or from infected ports, are going, this being necessary in order that such persons may be kept for a short time under observation. It was because this principle broke down under our original Cholera Order that a new one was issued by the Local Government Board, giving

the port medical officer of health power to refuse to any person permission to leave the vessel unless that officer was satisfied as to the address given. It will be obvious, in view of the experience of the past few weeks, that the addresses now being provided for these aliens ought not to be regarded as satisfactory, and so long as such people come from infected ports it is earnestly to be hoped that port health officers will strictly fulfil the important duty which has been imposed on them. It is announced that Hamburg has for one or two days been free from cholera; but this does not mean that Hamburg is no longer an infected port. Indeed, the announcement comes together with a statement that a number of cases of cholera did not, after inquiry, turn out to be cholera of the severe sort that had hitherto prevailed. We do not know how far this statement was based on the result of bacteriological investigations, but we sincerely trust that the occurrence at the fag end of an epidemic of certain cholera attacks which are not bacteriologically on all fours with cases that were more typical during the height of the epidemic will not for one moment lead, on the part of our health authorities, to any relaxation in stringency as regards the interpretation of our Cholera Orders. Hamburg must for some time be a city which contains the cholera infection, and it must therefore be regarded as an infected place. And so long as this is the case people have no right to expect that they will be allowed to enter London with dummy addresses and then effectually to hide themselves from all further observation and control in the worst slums of our great city. We believe we are right in saying that Dr. Collingridge has, in view of what has transpired in this matter, determined on requiring a rigid compliance with the regulations, and we trust that no health officer of a port which is in communication with Hamburg or any other infected place will accept as satisfactory anything in the way of addresses unless the circumstances are such as really to "satisfy him." The time may not be distant when Hamburg must for public health purposes be, provisionally at least, regarded as no longer "a place infected with cholera." Then this immigration can no longer be prevented for the same reasons that have led to its discontinuance for several months past. But with this the health officer has no concern; he can only deal with the matter in so far as public health is concerned; and it will be for the State to decide whether, on other than health grounds, the growing immigration of destitute aliens into the metropolis ought to be controlled.

### THE LORDS' COMMITTEE UPON METROPOLITAN HOSPITALS.

THE long-expected report of the Special Committee of the House of Lords upon the hospitals of the metropolis has now been made public, and attention will be directed with no small amount of interest to the conclusions which it embodies. It may be said at once that it does not point to legislation on any large scale. The Lords have come to the conclusion, fully justified and even necessitated both by the facts of the case and the evidence submitted to them, that the administration of the hospitals of the metropolis is too large and intricate a matter, and too well managed upon the whole as matters stand, to be with any public advantage taken over by the Government. Moreover the public interest, which is their main support, would not be increased, but diminished, if the State or a Government Department were interposed between the charity of the public and its objects. The proposal with which the report concludes concerning the appointment of a central board with general powers of supervision points to legislation. This proposal has been already considered in the columns of THE LANCET, and space does not serve for a reopening of the discussion to-day. This, together with some other points of interest in

the report, will be treated of in detail later on. At the present moment we desire to draw the attention of our readers to the document itself and the digest of it which appears upon another page, as a preparatory step to the fuller discussion upon which we propose to enter at a later date.

#### INTERNATIONAL MEDICAL CONGRESS, 1893.

At the request of the President and general secretary Sir James Paget has undertaken the formation of an English committee to aid the executive of the Congress in such ways as may prove practicable. A preliminary meeting was held at 1, Harewood-place, on Friday, Oct. 28th, to which the following gentlemen were summoned: The Presidents of the Royal College of Physicians of London, of the Royal College of Surgeons of England, of the Medical and Chirurgical, Clinical, Pathological and Medical Societies, Sir Joseph Lister and Sir William MacCormac. Present—Sir J. Paget, in the chair; Sir Dyce Duckworth, Sir George Humphry, Mr. Hutchinson, Sir W. MacCormac and Mr. Makins, acting as secretary. It was decided to invite the presidents of public bodies and societies representing the various branches of medicine, together with representatives from the universities and provincial towns possessing medical schools, to form a committee. It was stated that Messrs. Cook would arrange for special transit of a party of not less than sixty members, could it be formed, and a letter was read from the general secretary, Professor Maragliano, to the effect that the French railway companies have agreed to give a reduction of 50 per cent. on all fares paid by members of the Congress travelling through France. The names of the members of the committee will be published shortly and a general meeting will be called. The committee will be glad later to give any information in its power to intending members of the Congress through its secretary. As already announced, the Congress will meet at the end of September, 1893.

#### AN UNSATISFACTORY CASE.

AN inquest was held on Oct. 4th by Mr. Hillman, coroner for East Sussex, touching the death of Jessie Nissen Shepherd, a widow, aged fifty years. The deceased had resided for some years at Hove. Mr. C. J. Smith, surgeon, identified the body. Mr. McNiece, of Carshalton, was her regular medical attendant. About twelve months since Mr. McNiece suspected aconite poisoning and broached the subject to his patient. During her fatal illness, which lasted three weeks, Mrs. Shepherd suffered from vomiting and other symptoms, which ended by death from convulsions. Again Mr. McNiece was suspicious that poison had been administered, and suggested to the certificated nurse on duty that it was arsenic. He directed her to search the house for poison. A bottle of white powder—afterwards proved to have been a cosmetic—was found. On grounds which, according to the finding of the coroner's jury, were insullicient Mr. McNiece went so far as to hint that a relative of the deceased might be the guilty person. Before Mrs. Shepherd died Mr. Smith and Dr. Ulthoff were consulted. These gentlemen came to the conclusion that the illness was due to Bright's disease and that the convulsions were of uræmic origin. Now, although Mr. McNiece had given utterance to his suspicions, he ultimately gave a certificate of death from uræmic poisoning. Very properly the relatives insisted on having a post-mortem examination, which was performed by Mr. Smith and Mr. H. H. Taylor. The left kidney was almost destroyed by obstructive dilatation. The right kidney was hypertrophied and pale on section, but the capsule was not adherent. There was an ovarian cyst containing three pints of purulent matter. The cyst had contracted and there were marked adhesions. There were no signs of irritant poisoning in the stomach or elsewhere. The powder before referred to,

as well as portions of the viscera, were forwarded to Dr. Stevenson, the official analyst, in the event of further inquiry appearing necessary. Dr. Ulthoff, Mr. Smith and Mr. Taylor were unanimously of opinion that the symptoms and death were due to natural causes. The jury endorsed this view, and to their verdict added a rider that Mr. McNiece was deserving of severe censure in giving a certificate if he did not honestly believe that what he wrote thereon was true. No one could blame Mr. McNiece for entertaining a suspicion of poisoning, even though based on an error of judgment. The symptoms of irritant poisoning are simulated by several diseases of natural origin, as the annals of forensic history abundantly prove. At the same time we cannot altogether hold him blameless for his subsequent conduct. So long as there remained a shadow of doubt in his mind he ought not to have given a death certificate, and the report of the inquest apparently shows that he had not entirely abandoned the theory of poisoning. But having given the certificate it was his bounden duty to have at once acknowledged that he had made a mistake and to have unreservedly withdrawn the aspersions he had cast on the members of the family mentioned at the inquest, who, under the circumstances, are entitled to much sympathy. We do not presume to say that the evidence was not sufficient to warrant the verdict and the rider, but it would have been still more weighty had the result of an analysis by Dr. Stevenson been forthcoming.

#### VENTILATION AT THE LAW COURTS.

THE ventilation of the Royal Courts of Justice affords a perennial subject of comment from the judicial bench and in the press, but if Mr. Justice Day is correctly reported to have said a few days since that "the pumping engine was out of order, and could only pump the stale air used a couple of days ago," it may be hoped that he was dealing with a very exceptional state of things. The perverse ingenuity which could design plant for the storing up and preservation of stale air strikes us as being a nuisance so uncommon that it need not be seriously complained of; but even so we have a keen sympathy with the unfortunate people who are condemned to spend the day in one of the Courts at the Strand whilst the ventilating machinery is out of order. Whatever may be thought of some explanations of the phenomena which under these conditions obtain currency, the phenomena themselves are distressing in the extreme and in no mean degree unwholesome.

#### DIPHTHERIA IN SCHOOLS.

WE are glad to see that the prevalence of diphtheria in the Yerbury-road Schools, Holloway, has been brought under the notice of the London School Board, and that the fact is receiving a searching investigation at the hands of the medical officer of health, Mr. Harris. No less than thirty deaths have occurred of children in this school since October last. This is a most serious state of matters and one which demands the most complete inquiry, not only into the sanitary condition of the school, but with regard to the houses from which the children come. The parish of Islington has a reputation for good health, and had, until lately at least, a good record as respects diphtheria. But no general healthiness will avail if diphtheria finds favourable local circumstances and plentiful gatherings of young children, who are its chief victims. The valuable statistical tables of infectious disease which we publish monthly show that such a neighbourhood as Hampstead, with a small general mortality, may have in some months a large proportion of diphtheritic cases. General Maberley did not seem to relish the suggestion that the schools were to blame, and argued that the epidemic was prevalent in London, that only rain-water pipes went under the schools, and that the sanitary inspectors had made no inquiry into the

health of the habitations of the children. Mr. Harris has traversed all these statements and on the face of them they are of that vague kind with which officials are apt to deceive themselves, and convey no definite information and no suggestion for remedial measures. The very point of the question, as we understand it, is that there is a special incidence of diphtheria in these schools, or in the children that frequent them, as compared with other children in the same neighbourhood, perhaps in the same families, and with children attending other schools in the same parish. This localisation of the disease is sometimes intense and significant and it is only by studying closely instances in point that our knowledge of the origin and mode of communication of this disease can be increased. The medical officer of health of Islington will have the gratitude of the public in his endeavours to get at the bottom of this outbreak, and the members of the School Board should do everything in their power to assist his endeavours.

#### MOLESCHOTT'S JUBILEE.

THIS eminent biologist and teacher, whose scientific and professorial activity is still unimpaired, though he completed his seventieth year on August 8th last, will celebrate his jubilee in Rome on December 16th. The committee organised *ad hoc* have wisely chosen this latter month for the ceremony, as many of Moleschott's old pupils and colleagues might hesitate to visit Rome, even to commemorate his jubilee, in the late summer. This premised, it is safe to predict, a highly interesting and, historically speaking, a profoundly suggestive symposium in the capital of Italy seven weeks hence. Not only has the personal history of Moleschott been a most eventful one, but the revolutions in science and speculation he has witnessed are among the most momentous of the century now closing. A native of Bois-le-Duc, he naturally went to the University of Utrecht for his education, which, in its preliminary stage, was solid enough for the weighty professional superstructure he proceeded to build upon it. Choosing medicine as his *métier*, he became a pupil of Mulder, the great pioneer of physiological chemistry, and it was in Mulder's house that he formed the acquaintance of another Dutch physician not less illustrious than himself, the ophthalmologist Donders. This was in 1844, when the discoveries of Schleiden and Schwann were but six years old, when organic morphology was beginning to be transformed, and when only in 1842 had appeared the great work of Henle which impressed on the revolution they had effected the character of a comprehensive and fruitful reformation. "Schwann and Henle," says Moleschott himself, "in examining the chemical nature of the tissues knew no means beyond acetic acid and water," and he recalls the sceptical look of Henle when in 1844 he told him that Mulder and Donders had determined on delivering their histological attack with potash and sulphuric acid. Engaged for a brief space in private practice, Moleschott continued his laboratory work under Mulder, till in 1847 he was called to Heidelberg, where till 1854 he acted as *privat-docent* in physiology in its widest and most penetrating acceptation. Then it was that his powers as an investigator and expositor, not only in his prelections, but in his "Physiologie der Nahrungsmittel," his "Physiologie des Stoffwechsels," and his "Lehre der Nahrungsmittel," drew the attention of the scientific world by their bold and trenchant criticism of orthodox chemistry and physiology. Liebig was the main object of his attack, and when he demonstrated many of the great man's positions to be quite untenable and even mischievous to science he incurred displeasure in high quarters, and received a very broad hint that persistence in his polemics would be followed by the withdrawal of his permission to teach in public. He then quietly withdrew

to Switzerland, not, however, before bequeathing to Germany a controversy which did not cease till Liebig's too despotic authority had been reduced to juster and sounder limits. In Zurich he more than maintained the high reputation he brought from Heidelberg, and it was while there in 1861 that, in compliance with an old-standing invitation from Cavour, he left for Turin to undertake the duties of the physiological chair. His success was speedily apparent, and in turning out such pupils as Mosso and Bizzozero he soon showed of what immense value was his influence in the subalpine school and how amply Cavour's sagacity was justified in forcing "this *novus homo*" on Piedmontese science. Shortly after Rome became the capital of United Italy Moleschott was called to the chair of Physiology in the Sapienza, and there again he has outlived the prejudices that always beset a foreigner and outsider even in the domain of science, till in the ever-widening circle of distinguished and devoted pupils he has now a phalanx of admirers and vindicators that render him proof against all local attack or Chauvinistic disparagement. Indeed, the promoters of the imminent celebration of his jubilee whose names occur in the list now before us are, many of them, not only Italians but Romans, who as colleagues or contemporaries or pupils have learned to appreciate his work and to honour the worker. No one, indeed, at all familiar with Italian medical teaching as it was twenty-five years ago can fail to understand the wholesome, the reinvigorating influence of this Teutonic importation into a Latin atmosphere. His thoroughness, his philosophic breadth of view, his conscientious exhaustion of detail before proceeding to generalisation—all these were lessons greatly wanted by the Italians, who were perpetuating the effete traditions of the early decades of the century. Nor was Moleschott wanting in those literary graces and accomplishments in which his predecessors, whether in Turin or Rome, preponderated. Like his friend and fellow-student Donders, an accomplished classical scholar and linguist, he endeared himself to the Italians by a proficiency in Dante and a power of quoting him opportunely and with an effect not often shared by the mighty Florentine's compatriots. Year by year his hold on young Italy has deepened and strengthened; he has won their admiration by his learning and expository power and their love by his devotion to the Italian cause and his sympathy with its healthy and steady evolution, while at the same time he has retained the esteem of his academical and professional colleagues by a geniality of disposition and a suavity of address not always associated with Teutonic antecedents. All these elements of popularity and influence combine to ensure for his approaching jubilee a success honourable alike to its promoters and to its hero, and we shall watch with no common interest the commemoration of a career which, begun in Utrecht, continued in Heidelberg and Zurich, transferred to Turin, and culminating in Rome, has, at every stage, been coincident with the advancement of biological research and with the strengthening of the bases of scientific medicine.

#### PHARMACOPŒIAL SYNONYMS.

THE arguments in favour of extending the list of pharmacopœial synonyms have frequently been brought under the notice of the General Medical Council by Professor Atfield, and much has been done in this direction towards ensuring uniformity in the composition of substances which are frequently sold under popular names. Uniformity of composition is indeed the only safeguard against serious misadventures. Nothing can be more dangerous than the sale of drugs by the same name, where the ingredients differ, especially if in one case the preparation has been "improved" by the entire omission of the principal active ingredient. Sick persons may take this compound in increasing doses with impunity and thus incur very serious risks if on any occasion

they are elsewhere supplied with a specimen which has not been "improved." Those responsible for changes in the Pharmacopœia are fully alive to these risks, but that their work has not yet been generally appreciated or even recognised is obvious from the recent proceedings at the North London Police-court. A herbalist was summoned under the Food and Drugs Act for "selling a substance called paregoric which was not of the nature and substance demanded by the purchaser." Possibly it was originally intended to prosecute for the unlicensed sale of a drug containing opium, but no opium was found in this substance, and the prosecution under the Food and Drugs Act should have held good, if it could have been proved that the legal composition of paregoric had been defined by the admission of this name in the Pharmacopœia as a synonym for *tinctura camphoræ composita*. The counsel who defended maintained that "there was no substance called paregoric in the British Pharmacopœia, either of 1885 or in the edition of 1889," and, in the absence of rebutting evidence, the case was dismissed. Professor Atfield, the annual reporter on the Pharmacopœia to the Medical Council, whose painstaking work has so often been favourably noted in the columns of THE LANCET, may well feel aggrieved that this evidence was not forthcoming, since, as he explains in a letter to *The Times*, paregoric was inserted in the third reprint of the British Pharmacopœia in November, 1888, and in the gratis list of corrections issued in the same month as well as in the fourth and fifth reprints. Special attention was drawn to this insertion in the prefatory notice to the reprint of 1888; hence the omission of evidence to this effect at the time the case was heard must remain a mystery.

#### PETITION TO THE MEDICAL COUNCIL *IN RE* MEDICAL AID ASSOCIATIONS.

WE are asked to say that the following petition has been prepared, at the instance of the Medical Defence Association, for presentation to the General Medical Council at its approaching meeting on Nov. 22nd. Any registered medical practitioner approving it and wishing to add his name is requested to address a card to Mr. Ernest Hugh Fitzpatrick, L.R.C.P. Edin. &c., 122, Moseley-road, Birmingham, with the authority to add the name (which should be given in full, with qualification and address) to the petition. The petition reads as follows:—"To the president and members of the General Council of Medical Education &c. This petition of us, the undersigned duly registered medical practitioners, sheweth—that the modern system of medical practice conducted by the ostensibly philanthropic institution designated 'Medical Aid Association,' and similar bodies, is degrading to the profession and injurious to the public. And your memorialists pray that your honourable Council will take this increasingly important question into your consideration, and take such steps as may appear necessary in order to bring about an amendment of the evil.

#### SERVANTS' ACCOMMODATION.

IT would be folly to think of obliterating entirely the distinctions of privilege which belong to the position of a master or a mistress, and certain social amenities may reasonably be allowed to the latter which are not equally accessible to their domestics. In making this admission, however, it must be remembered that it is true only with limitations. It applies to many matters of dispensable comfort. It does not apply to participation in the absolute necessities of life. It cannot be used as a sanction for indecent and unwholesome herding underground such as occurred in a case lately reported by Mr. Wynter Blyth, in which three domestic servants were literally stowed away overnight in mere cellars, under stairways—damp, sunless and unventilated. Such wretched

accommodation, it is to be hoped, does not often fall to the lot of young persons in service, and no one could, with any pretence of logic, dispute the justice of serving their employers with the vestry order issued in this instance. It is certain, notwithstanding, that in this very matter of house-room custom leaves much to be desired. The term "servants' accommodation" does not necessarily indicate a fixed measurement of even 600 cubic feet, the minimum compatible with healthy conditions, for each person. Ventilation and cleanliness are usually but little considered, though the blame for such neglect must be shared by the servants themselves. The resulting consequences upon health are matters of daily observation. It is therefore clearly to the advantage of householders to see to it that the domestic reforms called for in the circumstances are carried out. Failing such action on their part, there appears to be no alternative but the far greater inconvenience entailed by official interference.

#### ISOLATION ARRANGEMENTS AT PLYMOUTH.

A GOOD deal of discussion is going on at Plymouth with reference to the question of isolation hospital provision, the immediate cause of the discussion being the inability of the Town Council to isolate a case of scarlet fever when such isolation was first needed. The rights and wrongs of the individual case are unimportant compared with the fact that the Corporation of Plymouth have for so many years delayed the provision of adequate accommodation for the important town for which they are responsible, the delay having taken place under the shelter of various pleas, including the refusal of the Local Government Board to approve of a loan to carry out a scheme which, in their opinion, seems to have involved failure. At last this difficulty has been removed by the preparation of new plans which have been submitted for approval and which it is anticipated will meet with the necessary consent. It is much to be hoped that no needless delay will be allowed to arise on the part of either the central or the local authority, for the absence of adequate means for isolating cases of infectious fever in Plymouth has long been a reproach to that borough.

#### THE LESSONS OF THE ALPINE SEASON.

A SAD interest attaches to the statement, lately published in the daily press, that the whole number of fatal mountaineering accidents in Europe during the present year amounts to thirty-two. This total perhaps is not very great when we compare with it the number of those who have employed the past season in Alpine climbing or the risks which they must necessarily incur. When, however, we learn that the unfortunate persons who thus lost their lives were in twenty-six cases unattended by any guides whatever, the tribute thus exacted of healthy recreation must appear unduly large. Suspicions of rashness and incompetence will not be set aside. It is true that all climbers are not rash, nor all routes hazardous; but it can hardly be disputed, in the face of such facts as those above stated, that skilled instruction and assistance are still too little utilised. Without such aid there must be an inevitable tendency to misunderstand conditions of weather, season and ground, which are, especially to the tyro, matters of the gravest moment. The ambition to scale a great peak offers to such especially a dangerous attraction, and it is characteristic of the humility of experience that more mature men prefer to begin a season with one or two easy ascents. Physical capability is a question for individual and very careful consideration. Almost anyone may visit Switzerland, but it by no means follows that anyone may risk the effort and exposure of a day, or perhaps two days spent in ascending a peak. The calamity which overtook the late Professor Nettleship and his party affords a melancholy example of the uncer-

tainies attending even a comparatively ordinary effort in mountain climbing and the endurance which it may entail. Such considerations ought to teach the un wisdom of hasty action in matters of this kind, and, above all, the fact that self-reliance with inadequate knowledge is no better than foolhardiness.

#### MEETING OF THE GENERAL MEDICAL COUNCIL.

THE General Medical Council will meet on Tuesday, Nov. 22nd, at two o'clock. It is impossible not to see that the action and functions of the Council are becoming more and more matters of public interest. And many considerations lead to the conclusion that at the approaching meeting the Council will have to deal with difficult questions respecting not only the professional conduct of registered practitioners, but concerning the safety and welfare of the public. We may take an opportunity before the meeting of the Council of considering the form in which these questions are likely to arise, though in the absence of the programme of business we can only conjecture.

#### RAG IMPORTATION.

ALREADY the effect of the various rag orders which have been drawn up by the Government as precautionary measures against cholera is being felt in the heavy woollen district. It is reported that manufacturers have been obliged to withdraw from their patterns all goods made from foreign rags, and that for certain classes of goods particular rags (now prohibited) are exclusively required. A request has been made by northern Chambers of Commerce that the Local Government Board should permit the landing of properly disinfected or carbonised rags, and that the prohibition of rags from France, Holland, Belgium, and States of Germany, unconnected with Hamburg, should cease in November. These are far-reaching requests which will doubtless be duly considered by the Government. But no selfish local commercial interests should be allowed to intervene between the public duty of the Government and the general interests of the population of this country that would be likely to suffer from an importation of cholera.

#### SCARLET FEVER IN BOARD SCHOOL CHILDREN.

THE old story of a coach-and-four being driven through any Act of Parliament finds its latest illustration in the easy evasion by parents of the Notification Act and the efficacy of the simple plea of ignorance. Three parents have been summoned before the magistrate of the South-Western police-court for exposing their children while suffering from scarlet fever and also for neglecting to notify. None of the children had medical attendance, and the excuse of the parents was that they did not know their children were suffering from scarlet fever. Dr. Little, chairman of the sanitary committee of the local board, gave evidence, and said the symptoms were unmistakable. Cases multiplied in the neighbourhood and suspicion fell on the local Board school. The mistress of the school sent to the sanitary inspector, expressing her belief that one of the children in the school had scarlet fever. Both the inspector and Dr. Little went to the school and found there were no less than three cases in a state of active and obvious peeling. Two of the children had gone continuously to school, the third had been kept at home on account of "a sore-throat and cold." Dr. Little has kindly given us further particulars in a letter. The schools have been closed. Between thirty and forty cases have occurred, and hospital accommodation has had to be supplied. The cost to the ratepayers is estimated to be between £300 and £400. The magistrate (Mr. Denman) expressed an important opinion. Dr. Little had given evidence that he could not say that he believed that the Parents knew

their children had scarlet fever; but he thought they had shown great carelessness, as there must have been a rash and the desquamation was very noticeable. Mr. Denman said he would like to see an Act passed making parents responsible whether they had a guilty knowledge or not. This is what it must come to. The sense of responsibility in parents whose children are suffering from diseases so mischievous to others must be quickened. There is no excuse in these days for parents who neglect their duty in this respect when medical advice can be so easily procured.

#### THE FOUNDLING HOSPITAL.

THE secretary of this hospital reports that the outbreak of scarlet fever there has not been virulent, but proceeds to state that since last March 200 children have suffered from the disease. This seems a large number, and points strongly to the need of some isolation building. The secretary states, too, that the drainage was remodelled in 1886, and has been recently pronounced satisfactory by Dr. Sykes, the health officer of St. Pancras. The latter writes to *The Times* to correct this rosy view, and to state that he had reported that the grease trap required alteration, that all waste-pipes should be cut off from the drains and sinks removed from wards and dormitories. He had also strongly advised that an isolated infirmary and probationary ward should be constructed. We trust, with Dr. Sykes, that the committee of this excellent institution has seen fit to carry out the above suggestions, and that there will be no recurrence of scarlet fever, which has excited so much comment.

#### THE STOURPORT MEDICAL AID ASSOCIATION.

A CORRESPONDENT dating from Aston, writing to the *Birmingham Daily News*, says that in the Stourport Medical Aid Company there are, or have been, all the Dissenting ministers, one solicitor, four members of the local board, nine-tenths of the publicans, 50 per cent. of all the tradesmen (including large drapery houses), all the coal merchants, many owners of house property and a large number of farmers. The surgeon receives less than 1s. 11d. per member. He is said to be no better off with a membership of 3058 than when there was only a membership of 2000. It is lamentable that respectable and intelligent men should continue in associations so to "sweat" and to starve a liberal profession. We cannot pretend to see what advantage they gain by it or hope to gain. There is no compulsion in them so to act. They cannot maintain that there is any justice or adequacy in such terms. It is of course lamentable that medical men so poor either in spirit or purse should be found to take such appointments, to the ruin of their profession. But this does not acquit ministers of religion, publicans and thriving tradesmen.

#### THE POLLUTION OF THE AIRE.

IT is well known that the West Riding County Council have for some time past been desirous of putting an end to the disgraceful and well-nigh intolerable state of the river Aire, which is fouled to an almost incredible extent with sewage and trade refuse. With a view to this end a conference was organised at Leeds last week between the Sanitary Committee of the County Council and representatives of the sanitary and conservancy authorities in the basin of the Aire and its tributaries. There seemed to be a unanimity of opinion that the sewage pollutions ought to be forthwith dealt with, and that as regards trade refuse steps ought at once to be taken to ascertain how this may best be treated or disposed of so as to avoid pollution of the river. Notwithstanding the apparent concurrence of opinion, we almost fear that nothing very immediate is in prospect. Leeds and Bradford claim that since they are county boroughs they are not concerned with any

conclusions at which the County Council may arrive; trade interests have probably influenced the decision that the sewage difficulty should be first disposed of; and even the most successful of all means for delay—namely, a Royal Commission—has been suggested in a resolution. The alternative of a Conservancy Board with adequate powers seems to offer a far more reasonable chance of successful and fairly prompt action, and we trust that due consideration will be given to this alternative. Under any circumstances, the West Riding County Council deserve credit for the action they are taking, and it is to be hoped that they will receive local and imperial help in prosecuting the task they have undertaken.

#### BAD MEAT AT PRESTON.

It is alleged that this town has been used as a dépôt for diseased meat. This state of things too has, it is said, been allowed to grow up in spite of, and indeed with, the connivance of certain officials. It was stated that a considerable trade in distinctly bad meat had taken place in Preston, and one member of the Town Council connects the abnormally high death-rate of Preston with the above-mentioned fact.

#### REMOVAL OF TUMOUR FROM THE SPINAL CANAL.

LAST week, in King's College Hospital, Mr. Watson Cheyne removed from a patient a large myxomatous tumour, which was situated in the spinal canal at a portion corresponding with the lower part of the dorsal and the upper lumbar regions. The nature of the tumour and its exact position had been accurately diagnosed by Dr. Ferrier. The growth was encapsuled and was easily removed. Unfortunately, the patient died thirty-six hours after the operation.

#### DEATH FROM GODFREY'S CORDIAL.

THE Borough Coroner of Leeds lately held an inquest on a child six days old which had died from an administration of Godfrey's Cordial by its mother as it seemed to be in pain. Mr. Hawkyard, a surgeon, said he found it collapsed and blue. He said the preparation contained opium and was not fit to be administered to so young a child. Of course this is so. We do not blame the mother so much as the state of the law which permits the sale of such poisons by chemists.

#### SMALL-POX OCCURRENCES.

AMONGST the places in which small-pox is either prevalent or new attacks are occurring are Halifax and its vicinity, Stamford, Stockbridge, Warrington, where the outbreak is a serious one, Hipperholme, Wyke near Bradford, Melton, where it has appeared in the workhouse; Scarborough, Daventry, Higham-Ferrers and Leicester, where three cases have quite recently occurred.

#### NEW PRODUCTION OF BLEACHING POWDER.

THE researches of Mr. Ludwig Mond have again been rewarded with commercial success. Some two years ago the chemical world was startled by Mr. Mond's discovery of the remarkable and unexpected carbonyl series, and now it appears he has succeeded in recovering the chlorine from the alkali waste in the Solvay or ammonia-soda process. It will be remembered that in the manufacture of soda by this process common salt is treated with ammonium bicarbonate, sodium bicarbonate and ammonium chloride being formed by double decomposition. The bicarbonate of soda is either crystallised out as such or subjected to heat with conversion into normal carbonate. The by-product, ammonium chloride, to which this new discovery relates, was previously heated with lime to recover the ammonia, the calcium chloride being thrown away, but it would

seem now that the chlorine itself can be saved. The ammonium chloride is crystallised out, dried, volatilised and passed over oxide of magnesia, so disposed as to present a large surface; the chlorine goes to the magnesium, the oxygen of which forms water with the hydrogen of the chloride, and ammonia is carried forward in the free state. The reverse process is now instituted, but air is passed over the magnesium chloride, which is reconverted into oxide, and the chlorine is used for the production of bleaching powder. The process is said to be actually at work on the large scale, so that the questions of cost and fuel consumption have no doubt been satisfactorily solved.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Basle.*—Dr. A. Jacquet, Assistant in the Medical Clinic, has been recognised as *privat-docent* in Experimental Pathology and in Pharmacology.

*Brussels.*—Dr. Warnots has been appointed Professor of Operative Medicine in succession to Dr. Tirifahy, who has resigned.

*Cracow.*—Dr. Braun has been recognised as *privat-docent* in Midwifery and Gynaecology.

*Dorpat.*—Dr. A. S. Budilovich of Warsaw has been appointed Rector, in succession to Dr. Meikoff, whose health has obliged him to resign.

*Gratz.*—Dr. Zoth has been recognised as *privat-docent* in Physiology.

*Jena.*—Dr. Ludolf Krehl of Leipsic has been appointed Professor and Director of the Medical Policlinic. Dr. Wagenmann of Heidelberg has been offered an Extraordinary Professorship of Ophthalmology, with the charge of the eye clinic.

*Lausanne.*—Dr. Eugène de la Harpe has been recognised as *privat-docent* in Climatology and Balneology. Dr. Paul Demiéville has been appointed Extraordinary Professor in the Policlinic.

*Praque (German University).*—Dr. Edmund Münzer has been recognised as *privat-docent* in Special Pathology and Therapeutics.

*St. Petersburg (Military Medical Academy).*—The contest for the chair of Special Pathology and Therapeutics lately vacated by Professor Manassein, editor of the *Vrach*, has been unusually severe. The result is that the Professorial Conference has by a considerable majority selected Dr. Nilus Sokoloff.

THE Regius Professor of Medicine of Oxford University has given notice that the examination in Human Anatomy and Human Physiology at the first examination for the degree of Bachelor of Medicine will commence on Wednesday, Dec. 7th, at 10 A.M., in the University Museum. In consequence of a recent change of statute it is no longer necessary to forward any certificates or testamurs.

ON Thursday, Oct. 27th, at a special meeting of the Council of Epsom College, the following resolution was unanimously adopted: "That the report of the school committee (which we print on page 1067) on the dietary at the College be received, adopted and its recommendations carried into effect; and that copies be forwarded to the parents of all boys at the College and to the leading medical journals."

DR. DAVID CALDWELL M'VAIL of Glasgow has been appointed Crown representative for Scotland on the General Medical Council, in lieu of the late Sir G. H. B. MacLeod. Dr. M'Vail has already been a member of the Council as representative of the faculty of Physicians and Surgeons of Glasgow from June 7th, 1886, to April, 1888, when he was succeeded by Dr. Hector Cameron.

At the autumn general meeting of the Governors of St. Mungo's College held on Oct. 27th, the Professor of Systematic Surgery, Mr. David N. Knox, M.A., M.B., was appointed Professor of Clinical Surgery in room of Professor William Macewen, LL.D., who had resigned in consequence of his appointment as Professor of Surgery in Glasgow University; and Mr. Henry E. Clark, M.R.C.S., Professor of Anatomy and Dean of the Faculty of Medicine, was appointed Professor of Systematic Surgery, vice Professor Knox. Applications for the chair of Anatomy should be lodged with the Secretary on or before Dec. 1st next.

OWING to the death of Lord Sherbrooke a vacancy has occurred in the Senate of the University of London, and in accordance with precedent his place will be filled by a graduate in science or medicine. Dr. W. J. Collins, M.S., B.Sc., F.R.C.S., is a candidate, and probably other names will shortly be announced.

THE next meeting of the Odontological Society of Great Britain will take place on Nov. 7th, when Mr. Storer Bennett will read a paper on Some Mechanical Devices for the Retention of Artificial Dentures, and a communication will be given by Mr. F. Newland-Pedley on Inverted Lower Canine Tooth erupting below the Chin.

THE Royal Commission on Vaccination held another meeting on Wednesday last, Sir James Paget presiding. Dr. J. C. M'Vail was examined and gave evidence in favour of vaccination. The Commission then adjourned until Wednesday next.

THE Royal Medical Benevolent College has received a donation of £1000 from a friend who does not wish his name to be known.

PROFESSOR VIRCHOW has been appointed an honorary member of the Imperial Russian Natural Philosophy Society.

## HOSPITAL FEDERATION IN LONDON FOR CLINICAL PURPOSES.

By JOHN ERIC ERICHSEN, LL.D., F.R.S., F.R.C.S. &c.

In the Report of the Royal Commission on a Teaching University in and for London it is stated that the opportunities for clinical instruction that exist in the metropolis are "unrivalled." That this is so admits of no doubt, and that these unrivalled opportunities are not utilised to anything like their full extent is equally certain. No evidence was given before that Commission to show how these admittedly unrivalled opportunities could be utilised with more advantage to the student than they now are, and the report is silent on this most important point. I trust that I may therefore be excused for venturing to make some suggestions towards the attainment of so desirable an end. I have visited at various times most of the great medical schools in Europe and in the United States of America, and I can without hesitation affirm that the word "unrivalled," used in the Report of the Royal Commission as descriptive of the clinical opportunities presented by London, is the correct designation. No city in the civilised world offers such a wealth and so varied an abundance of clinical material as does London, both as regards general medical and surgical practice and particular forms of special disease, and yet so little are these unequalled opportunities utilised that English medical students annually resort in large numbers to the cliniques of Paris, Vienna and Berlin in order to obtain that professional knowledge to which access is denied them in this metropolis. They can there follow without restraint and at little or no cost the teaching of the most eminent physicians and surgeons and of the most able specialists of the day. They return skilled in

foreign methods of diagnosis and of treatment, but with little knowledge of those that are to be learnt in this great city, outside the walls of the particular hospital in which they have been educated; for to the vast and varied stores of clinical information that here lie within easy reach access is practically denied, and indeed of their very existence they may be ignorant. The student is obliged to go abroad for the purpose of obtaining advanced and special clinical instruction, not from any lack of material here, but in consequence of its inaccessibility and the absence of all proper organisation for its study and utilisation. In London he is absolutely restricted to the teaching of the physicians and surgeons of the one particular hospital to which, as a pupil, he has attached himself and for which he has paid his fees. The invaluable instruction to be gained from the vast practical experience and profound scientific attainments of such teachers as a Jenner or a Gull, a Paget or a Lister, or the skill to be acquired by being the daily witness of the consummate methods of a Liston, a Fergusson, or a Bowman, are denied him here unless he happens to have entered as a pupil to the hospital to which one or other of these masters of their science and art is at the time attached. To the practice of that one particular man he is admitted. From that of the others he is shut out, unless he possesses the means and has the inclination to pay a second or a third time the very considerable fee for "hospital attendance." This, indeed, is a student's question, and the matter should be considered from a student's point of view rather than from that of the teacher in the medical school or the governor of the hospital. The London student has a right to expect that he shall not be placed at a disadvantage by the refusal freely to open to him those vast stores of clinical observation and study that are to be found in such unequalled and profuse abundance in London, and thus to be compelled either to starve his craving for knowledge if he remains here or to satisfy it at the cost of going abroad. There is no other alternative. But may not this state of things, so injurious to the best interests of medical education, be corrected? Is it not possible to place London not only on a level with but far ahead of all other European capitals, as a great school of clinical medicine and surgery in the widest sense of clinical teaching as well as in its more special departments? I cannot doubt that with proper organisation of the enormous opportunities for clinical study that exist in London, and by rendering these accessible to the advanced student and young practitioner, the necessity for foreign study will no longer be felt, and that the cliniques of London will attract in their turn students not only from all parts of the United Kingdom, but from our colonies, the United States of America and even the Continent of Europe. Those who may wish for special opportunities of study and of instruction in every department of clinical medicine and surgery will come here, and the cliniques of London will be placed in that pre-eminent position which their physicians and surgeons have so long and so ably maintained. The value of a clinique is determined by three considerations. These are: first, the amount of clinical material; second, the character of the cases; and third, the ability of the teachers. Few, even amongst the members of the medical profession, are probably aware of the immense amount of clinical material that exists in London. The vast number of diseased and injured persons of the class that seeks cure and relief in our hospitals, infirmaries and medical charities of all kinds far exceeds that of any other city in the world. The population of the county of the city of London equals in numbers that of the whole of Scotland and exceeds greatly that of many continental Sovereign States. Engaged in every possible kind of industrial pursuit hazardous to life or limb, and injurious in many special ways to health, it would of necessity furnish an enormous amount of injury and disease. To this must be added a very large number of persons suffering from serious or special forms of disease who are constantly attracted to London from all parts of England, and even from the colonies, by the world-wide reputation of its hospitals, both general and special, and by that of individual members of their staffs.

There are eleven general hospitals in London of sufficient size to be recognised by the Royal Colleges as schools of clinical medicine and surgery. In these eleven clinical hospitals there is a total of 4542 beds.<sup>1</sup> The number of beds varies greatly, from 750 in the largest to 180 in the smallest of these hospitals. Besides these there are several smaller general hospitals, such as the Great Northern, the Metropolitan, the West

<sup>1</sup> This number is taken from the list published in the British Medical Journal for Sept. 3rd, 1892.

London and the North-Western Hospitals, which, although not recognised by the Examining and Licensing Corporations as schools of medicine, afford abundant opportunities for clinical study and the acquirement of practical experience. The amount of clinical work done at a hospital cannot be measured solely by the number of its beds. The out-patient departments which have now grown to enormous and almost overwhelming proportions in all the London hospitals furnish an abundant supply of interesting and instructive cases, more particularly of various special forms of medical and surgical disease which do not require to be treated in hospital—such as affections of the eye, the ear, the skin and the throat—for which special clinics are now established in all the larger general hospitals. In addition to these there are special departments in the general hospitals for the treatment of diseases of women and children, and to all a maternity charity is also attached. The Poor-law infirmaries in the metropolitan area are very numerous and contain a vast number of beds. I find on reference to Churchill's Medical Directory for 1892, the most reliable source of information on such a subject, that there are no less than twenty-seven such infirmaries, containing an aggregate of 13,285 beds, or an average of nearly 500 beds. These are, in fact, general hospitals, and contain an immense amount of clinical material that now goes to waste, but that admits of being most advantageously utilised. Of its great value I can give no better proof than that of the work done by Sir Henry Thompson, who, when surgeon to the St. Marylebone Infirmary at the commencement of his brilliant career, made there a series of researches on the Diseases of the Prostate of the most important character; whilst his predecessor, Mr. Benjamin Phillips, F.R.S., found in the wards of the same infirmary the material which served as the basis of his work on Scrofula. These infirmaries contain inexhaustible material for the study of the diseases of advanced life, of childhood and of many special forms of disease, such as those of the skin. In early professional life I was a frequent visitor to the wards of the St. Marylebone Infirmary, which was then officered by Dr. Mayo, President of the Royal College of Physicians, Dr. Glendinning and Mr. Benjamin Phillips, F.R.S., and learnt much in them of diseases that are not usually met with in general hospitals. The special hospitals of London are very numerous. They are of two kinds: those that have been established by the benevolent public to fill a gap and a recognised want in the other charitable institutions, and those that have been founded by and, to use an American expression, are "run" by special practitioners. For obvious reasons such institutions as the latter are not suited for educational purposes or as schools for clinical instruction. But the special hospitals that belong to the first category are numerous, large, well equipped and officered by physicians and surgeons of the highest eminence and of acknowledged ability in their respective special lines of practice.

It would be impossible here to mention all the special hospitals that exist in London and might be made available for clinical instruction. But a few of the most important may be specified. Thus the seven "fever" hospitals for the reception of acute zymotic diseases contain (1892) a total of 2571 beds, often greatly augmented in periods of the prevalence of epidemics, as of typhoid or scarlet fever.<sup>2</sup> The two largest hospitals for diseases of the chest—viz., the Brompton Hospital for Consumption and the City of London Hospital—contain respectively 321 and 164 beds. The Moorfields Ophthalmic Hospital contains 100 beds, but as the vast majority of cases of eye disease admit of being treated as out-patients, it is in its external clinique rather than in its in-patients that the measure of its utility as a clinical school is to be found. The Cancer Hospital contains 120 beds and the Lock Hospital 155. Both these institutions contain valuable material for clinical study. There are at least eight special hospitals for children, containing an aggregate of 621 beds. Of these eight hospitals, two—viz., the hospital in Great Ormond-street, with 175 beds, and the East London Hospital, with 102—would be available for purposes of clinical instruction. There are five hospitals for diseases peculiar to women, containing an aggregate of 241 beds, which are chiefly devoted to the reception of patients suffering from diseases requiring surgical treatment. In addition to these there are eight lying-in hospitals. The National

Hospital for the Paralysed and Epileptic, in Queen-square, contains 175 beds, and is now thoroughly equipped for clinical instruction. There is one special hospital which I believe to be peculiar to London—I mean the Poplar Hospital for Accidents, an institution rendered necessary by the hazardous work carried on in its neighbourhood. It contains 51 beds. There is thus in the general and special hospitals alone an aggregate of from 8000 to 9000 beds available for clinical purposes. The asylums for idiots, imbeciles and lunatics are very large. The five asylums for idiots and imbeciles contain an aggregate of 6750 beds. Bethlem and St. Luke's Hospitals contain a total of over 500 beds, and the five public lunatic asylums specially connected with the metropolis have an aggregate of 12,705 beds.

In addition to the vast amount of clinical material that exists in London in its various large general hospitals, its infirmaries, its more important special hospitals, its maternities and its asylums for the idiotic and insane, and which might all be made available for the purposes of study and of instruction, there is much more to be found in the smaller hospitals and in the dispensaries which abound in the metropolis. These institutions, though highly useful for the purposes of private study and observation, are neither officered nor equipped in a manner that would render them available as clinical schools. They have accordingly been left entirely out of present consideration. It is not only the amount of the material available for clinical instruction that has to be taken into consideration in estimating the value of a clinique; its character must also be taken into account, and in this respect London will be found to be as far beyond all rivals as in the mere number of its patients. By the character of the clinical material I mean the importance of the cases of which it is composed, either as regards severity or rarity, or as presenting typical forms of disease. The high reputation of the metropolitan hospitals and the acknowledged eminence of many members of their staffs have always attracted a large number of persons suffering from the more serious, special or incurable forms of medical and surgical disease to seek advice in the metropolis. This number has been largely increased of later years by the facility and cheapness of transit. Many provincial practitioners also prefer to send their more important cases for advice and operation to their old hospital and their old teachers in London, on whose judgment and skill they have reliance and with whose views they are acquainted. A considerable percentage of the in-patients in the London hospitals thus comes up to London for advice and operation. I find that at University College Hospital—with the details of which in this respect I am only acquainted—the proportion of the in-patients who come or are sent up from the provinces amounts as nearly as possible to 10 per cent. of the whole. But there is another potent factor in raising the standard of gravity in the in-patients of many at least of the London hospitals. It is their acknowledged insufficiency in point of accommodation for all of those who seek their aid. Hence a strict process of selection is adopted by the resident officers in the admission of patients, and only the most severe, urgent and important cases are admitted, all of those who can in any way be treated in the out-patient department and most of the chronic cases being referred to it.

Of the professional eminence and the special aptitude for teaching of the large body of distinguished physicians and surgeons connected with the London medical schools I need say nothing, as they are universally recognised and are beyond dispute. There is thus every element for the formation in London of the most important school of clinical medicine and surgery in the world. But to do this the material at hand must be organised and rendered accessible to the student. We will now consider how this can be done. The available clinical material that exists in London may be arranged in three groups of institutions—viz., the general hospitals, with medical schools attached, the larger and more important special hospitals, and the poor-law infirmaries and asylums. Of these, the eleven large general hospitals with their 4542 beds, their special departments and their maternities are by far the most important. They are the most important not only on account of the number of beds they contain and the character of the cases that fill those beds, but of the acknowledged eminence as practitioners and teachers of the great body of physicians and surgeons attached to them. Taken collectively and federated together, so that the instruction given in them should be opened to the advanced student, they would constitute a great clinical school of medicine and of surgery in all their branches that would be without an

<sup>2</sup> At the present time (October, 1892) these hospitals contain over 4000 cases of scarlet fever, diphtheria and typhoid fever.

equal in Europe. In this case union is strength. Taken collectively they are superior to all. But their weakness lies in their isolation, for, taken singly as separate and distinct clinical schools, many of them are inferior as regards number of beds, construction and equipment to some of the great provincial hospitals in this country, and none, not even the largest and most important, can claim superiority as clinical schools over those of the capitals and great cities of the continent of Europe or in the United States of America. The remedy is to be found in the abandonment of the system of isolation that at present exists, and which neutralises the immense and undoubtedly unrivalled opportunities for clinical study that are to be found in the great hospitals and other medical charities of London. For this should be substituted a system of federation for clinical purposes. For it is idle to speak of these opportunities as being "unrivalled" so long as the most important of them are cut up into as many distinct and separate fragments as there are hospital schools in the metropolis, and the remainder are scarcely, if at all, utilised; so that for all purposes of clinical instruction each hospital school is as completely separated from its neighbour as if it were at the Land's End or at John o' Groats house. Unless a system of federation for clinical purposes be substituted for that of isolation and the unrivalled opportunities that I have shown to exist be fully utilised so as to be brought collectively within reach of the advanced student and young practitioner, the medical school of London, great as it undoubtedly is, will never take that pre-eminent position which it is entitled to assume amongst the schools of Europe both by the acknowledged ability of its teachers or the immensity of its clinical opportunities. The system that at present exists in London is so well known as scarcely to require description. It is as follows:—The student "enters" to one particular hospital and continues a pupil of it till he has passed his examinations. He is limited to the practice of that hospital and to the clinical instruction of the medical staff connected with it. The fees that he has paid for these privileges are considerable, and he is shut out from attendance on the practice or the clinique of any other hospital unless he chooses to "enter" it and to pay another fee for clinical instruction. This, I need scarcely say, is very rarely if ever done. He continues through life, as a rule, attached to his own hospital, with the traditions of which he is imbued and with the practice of which alone he is acquainted. The choice of the hospital preferred by the pupil is usually determined by convenience of locality, or by some personal acquaintance with a member of the staff or some former student, rather than by any special regard to the merits of the particular hospital as a place of instruction, of which probably neither he nor his friends are competent judges. The evils arising from this condition of things are not felt in the earlier part of the student's career, but they become manifest later on. The five years' curriculum now required by the licensing corporations may be carried on anywhere, at any medical school in London or the provinces. Any medical school that is recognised by the Royal Colleges may be taken to be fairly equipped, and its teaching fully sufficient for carrying the pupil through his education up to a good minimum pass examination, such as that of the Conjoint Board or the M.B. of most British universities.

My remarks therefore do not apply to the pupil who is preparing for his examinations, but to the student in the subsequent and more important part of his career when qualifying for the M.D. degree or seeking to perfect his knowledge. Indeed, I consider it to be very important that the study leading up to the pass examinations should be carried on at one medical school only and under one set of teachers. The same subjects are taught in all the medical schools and cannot vary. But the method of teaching these subjects and the manner in which they are handled vary greatly, and this is true not only with regard to subjects that admit of much difference of opinion, but even of such as ordinary descriptive anatomy, which are little more than a mere collection of facts to be committed to memory. By going from one school to another the pupil would have to change his method, which would result in much confusion and loss of time. That faculty of sustained attention, also so important, but also so difficult of attainment by the young, would be likely to suffer. In any scheme of federation the larger and more important special hospitals—such as those I have already mentioned—should be included. Much valuable information is to be obtained in them in respect to the diagnosis and detail of treatment of the class of cases with which each hospital is specially con-

cerned. Much is to be learnt by the advanced student in the opportunity he would there have of observing and comparing large numbers of cases of allied diseases, and he would be able to do this under the most favourable circumstances, as many of the physicians and surgeons of the special hospitals are skilled and experienced teachers in the general medical schools. The twenty-seven Poor-law infirmaries offer—as has already been said—enormous and varied opportunities for clinical study. But their organisation and admission into any general scheme of medical education would be attended by some difficulties, owing to the nature of their government, and I would defer the consideration of this part of the subject to some other time, contenting myself for the present with merely pointing out the vast amount of clinical material stored up in these 13,285 beds, and in the vast opportunities for the study of mental diseases afforded by the great lunatic asylums in and around the metropolis. The establishment in London of a Teaching University to which the medical schools would be attached as constituent colleges would be a most favourable occasion for the federation (for clinical purpose) of the hospitals connected with those schools, and for the mutual interchange of students during the final two years preceding the examination for the M.D. degree, under certain restrictions to be agreed upon by the colleges and the Council of the University. The scheme that I would venture to suggest for the purpose of hospital clinical federation is briefly as follows: On the admission of a medical school as a constituent college of the new Teaching University it should become a member of the hospital federation. The admission of any given school as a constituent college would be voluntary, but a condition of such admission should be that it become federated, so far as advanced clinical hospital instruction is concerned, with the other constituent medical colleges. The federated hospitals should be open for the purposes of clinical instruction to all those students who intend to present themselves for examination for the M.D. degree of the new university, no student being admissible to such instruction until after having obtained a registrable qualification and only during the final period of two years of study; no student *in statu pupillari* being admissible to any other instruction than that which is given at his own particular hospital. Admission to the clinical instruction of the federated hospitals should be by ticket, to be issued by the university, for which no fee should be paid by London students beyond a small one, say of one guinea, to meet the expense of registration and to ensure the *bona fides* of the applicant. In the case of the provincial students who had not previously entered to the practice of any of the metropolitan hospitals an entrance fee should be paid to the university, the amount and disposal of which may from time to time be determined by the Council; or, by entering directly to the practice of one of the federated hospitals, he would be placed in the same position as a London student. In the case of the special hospitals that have become federated a small fee should be charged, such as is now paid for attendance on post-graduate classes, and as attendance on these hospitals is now recognised by the Royal Colleges as part of their five years' curriculum, no difficulty need be anticipated here. Special arrangements would require to be made with the metropolitan infirmaries and asylums for the admission of a limited number of students to their practice and residence in an official capacity in these institutions, and at the larger federated special hospitals might be held to count for a part at least of the final two years' clinical study. The requirement from the candidates for the M.D. degree of a residence in London and attendance for a period of two years at one or more of the colleges of the new Teaching University of London is in strict conformity with the rule of every other teaching university in Great Britain. The four Scottish universities all require residence as an essential preliminary to admission to examination for their degrees. So likewise do the four teaching universities of England. On what ground, therefore, can this be refused in the Teaching University for London? If the principle of residence be right for Edinburgh and Glasgow, Aberdeen and St. Andrews, for Oxford and Cambridge, Durham and Manchester, how can it be wrong for London? If not necessary for the London student, on what ground can its necessity be urged for those of other universities of a similar scope as that for London? The M.D. degree should not be given before the age of twenty-four, two years subsequently to the time at which the registrable qualification has been obtained. These two years should be devoted to the attainment of proficiency in clinical medicine in the

federated hospitals and to the practical subjects connected with it. Two years so spent would be undoubtedly the most important in the career of the student. When once he has emerged from his pupilage and has obtained his registrable qualification he may disembarrass his mind of a vast amount of detail with which it has been encumbered for the purposes of passing successfully the dreaded ordeal of the various examinations leading up to the attainment of his diploma, and he is then free to devote himself specially to clinical medicine and to such other scientific and practical work for which he may have special aptitude or natural inclination. The whole of the day cannot, and need not, be spent in clinical study and observation. Much time should be given to it, but much may also be reserved for practical study and work in the laboratories of physiology, pathology, bacteriology, hygiene and forensic medicine. These scientific departments of medicine should occupy his attention as well as clinical medicine, for in them should his examination for the M.D. be conducted, and to proficiency in them must he look for success as a scientific practitioner in future life. In the study of such subjects as those which are comprised in what are termed "post-graduate" courses the student will find the most useful and profitable employment during the final two years that should intervene between his ordinary "pass" and his ultimate M.D. examination. He will now have been emancipated from his own particular school—from that school of medicine in which he has received his education up to the period of his pass, and he will naturally seek for instruction in the higher and more scientific branches of his profession wherever the fame of the teachers is highest and the equipment of their laboratories the most complete. Should this be in his own school he will naturally remain there. Should superior attractions and opportunities present themselves elsewhere he will—if wise—not allow himself to be fettered by old ties and traditions, but get the best instruction from the best teachers and in the best equipped laboratories, wherever they are to be found. He will find that every clinical school presents some special distinctive feature or method of its own, differing perhaps widely from that to which he has heretofore been accustomed, but well deserving careful study and comparison. His horizon will be widened. He will learn no longer *jurare in verba magistri*, but to form juster conceptions in science and to take broader views in practice than he possibly could when confined to the narrowing influences of the teaching of one set of men and the traditions of one hospital only, and he will be led to form a clear and considerate judgment on men whose opinions, though differing from those of his own teachers, he may yet find not to be entirely erroneous or undeserving of consideration.

## THE THIRD REPORT OF THE LORDS' COMMITTEE UPON METROPOLITAN HOSPITALS.

The third and final report issued by the Lords' Committee upon Metropolitan Hospitals has now been made public and contains, in addition to a summary of the evidence submitted, the conclusions at which the Committee have arrived. These conclusions are conveniently distributed under a series of headings, and, although too voluminous for quotation unabbreviated, may be conveniently summarised as follows:—

### ENDOWED HOSPITALS.

In the case of the three endowed hospitals, the Committee are of opinion that the system of administration does not on some points compare favourably with that which exists at the other general hospitals. It throws too much power and responsibility into the hands of one individual, the treasurer; though at St. Thomas's Hospital a larger share in the administration is assigned to committees than at the other two. The Committee would suggest that in all these endowed hospitals the government should be carried on by a system of weekly boards and subcommittees.

### REMAINING GENERAL HOSPITALS AND SCHOOLS.

Their systems of management greatly resemble one another, and the evidence shows that they are generally well administered. The Committee note the enormous amount of work done by unpaid boards of managers and the care exercised, so far as the Committee are able to judge, in the appointment of their medical as well as other officers. The Committee desire to refer to the personal nursing dispute appearing in the evidence of the London Hospital. The authors of these charges were for some time nurses and probationers in this hospital, some of whom did not remain during the whole period of training, and of whom two at least stated grievances of their own which were not confirmed by the evidence; and the late chaplain, who for some

time before the termination of his connexion in that capacity with the hospital, had differences with the Committee both in these matters and also in regard to the performance of his own duties. The charges are on the whole, in the opinion of the Committee, not substantiated by the evidence. The evidence in regard to the injury to the health of the "sisters" appears inconclusive. The Committee consider that the difficulties would have been avoided had the Governing Board in charge of the hospital at that time not allowed their authority to fall into the hands of alarmed officers. In justice, however, to the London Hospital, the Committee wish to add that it is an admirable hospital, doing work in a part of London where it confers inestimable benefits upon a very large and very poor population. They therefore think it is deserving of the greatest measure of charitable support. The Committee recognise that it is advisable, under present circumstances, to maintain the individuality of these general hospitals, and they consider that the generous rivalry thus promoted tends to medical and administrative efficiency. The Committee suggest that the fact of not holding the diplomas of the Royal College of Physicians and Royal College of Surgeons of London should not exclude practitioners who have graduated elsewhere from becoming members of the staffs of the general hospitals in London.

### CONVALESCENT HOMES.

The Committee remark that the accommodation for convalescents in connexion with the large hospitals is insufficient, only two or three having convalescent homes attached to them; and that this want is met by the authorities of the hospitals subscribing, through the Samaritan Fund, to convalescent homes. Owing to the scarcity of accommodation the patients, although not thoroughly cured, are discharged if well enough to leave the hospital. In some cases these patients find their way to the Poor-law infirmaries; in other cases patients suffering from medical complaints have to be kept for long periods in a hospital, although they would recover more rapidly at a convalescent home in the country. Moreover, these patients have to be provided for in the hospital, to the exclusion of those who would be admitted were beds vacant. The Committee avail themselves of this opportunity to direct attention to this need, in the hope that more extensive convalescent accommodation may be provided by philanthropic effort.

### OUT-PATIENTS AND DISPENSARIES.

It is considered by the Committee that by the abolition of the out-patient departments medical education would be seriously interfered with, and, further, that on the whole it must be left to the authorities of the hospitals themselves to arrange the organisation of the out-patient department with the view of rapidly attending to the requirements of the public and of insuring as far as they can that the charities shall not be abused. The Committee are of opinion that the charities are not abused to any serious or appreciable extent, nor do they think that it was by any means proved that patients are carelessly treated, or treated by students instead of thoroughly qualified medical practitioners. On reviewing the evidence as to the different systems pursued by the different great general hospitals the Committee think that, on the whole, the system of limiting the number of out-patients per diem is the most convenient. The Committee consider that inquiries should be made wherever experienced officials think there is cause for suspicion, and that the patient should establish a *prima facie* case for charitable relief. Medical practitioners and the medical officers of free and other dispensaries should be encouraged as much as possible to take advantage of out-patient departments as centres for consultative purposes, and, from the evidence of many hospital witnesses and others, this is already done to a certain extent. In the case of dispensaries and practitioners the patient might be left in the hands of his medical adviser and not necessarily taken into the hospital.

### DISTRIBUTION OF HOSPITALS.

It was suggested that certain hospitals might be removed from places where they are not so much required to localities where the accommodation is deficient. The Committee cannot regard this suggestion as practical, but they would strongly advise that more hospital accommodation should be provided south of the Thames, and were it possible to find the site, and were philanthropic endeavours to be made for further accommodation for the sick in London, a large general hospital, say in the densely populated district of Camberwell, would no doubt be of extreme value.

### EDUCATION.

The Committee observe that a very useful field for medical instruction is at present closed to students—namely, the Poor-law infirmaries. It was the opinion of nearly every witness that these infirmaries could be usefully opened for clinical instruction. In this the Committee heartily concur. In addition to the large field for instruction which would thus be opened, they agree with the opinions expressed that the presence of students is to the practitioners stimulating, by reason of the observation and criticism which are brought to bear on diagnosis and treatment; and the evidence they have received shows that where a system of clinical classes of students is carried out under proper regulations the patients have no objection to students at their bedside.

### SPECIAL HOSPITALS.

Hospitals for certain diseases of patients—for example, for children—do not appear to the Committee to be open to the criticisms made on special hospitals. Lock hospitals form a separate subject for consideration. The Committee think that the nature of the disease and the character of the patients make it desirable that they should be treated in separate buildings, or, at all events, in separate wards from other patients. The Committee have had their attention particularly directed to the fact that patients in these hospitals are in the habit of quitting the hospital in a diseased state on such occasions as the Derby week, fairs &c., for the purpose of pursuing their avocation. The Committee recommend that provisions analogous to those which prevent a patient leaving a hospital when suffering under infectious diseases should be extended to certain venereal diseases. The Committee consider that the charge of abuse is substantiated in regard to some small special hospitals. This class of small special hospitals to which the Committee refer, of which examples appear in the evidence, the Committee do not consider of any real benefit either to the sick or to science. They appear to be carried on sometimes in inconvenient buildings or under insanitary conditions, and the Committee would deprecate the multiplication of such institutions.

In this connexion the Committee devote a paragraph to the Royal Hospital for Incurables at Putney, in which they recommend the introduction of reforms, including the appointment of a resident medical officer with general control in the absence of the committee, the appointment of a ladies' committee, the exclusive employment of hospital-trained nurses, the giving out of contracts to open tender, and a great increase of the general supervision by the committee of governors. The giving out of contracts by tender is a practice which they recommend for general adoption.

#### NURSING.

A certain amount of variety exists as to the hours of employment of nurses in the general hospitals in London. The Committee consider that eight hours' work, exclusive of the time for meals, is, as a rule, as much as should be required from nurses in these hospitals. In constructing future hospitals care should be taken that sufficient accommodation for nurses be provided to allow of the hours of nursing being reduced. They would suggest that every nurse in the large and busy hospitals in London should have at least two days off in the month, and that the period of holiday should not be less than three weeks; that not less than one full hour should be allowed for dinner; and while, on the whole, the food of the nurses appears to be good, yet, from the nature of the occupation of nurses, special care ought to be exercised that as well as being sufficient in quantity and in quality it should be served in an appetising manner. To bring about this end the Committee are strongly of opinion that at the nurses' dinner one of the head officials of the hospital should preside, and that the dinners should be frequently visited by members of the governing body. Nurses in the wards should not have their duties increased by doing menial work, such as scrubbing and cleaning grates and lavatories, or other services of a like nature. For that purpose, as is the case in most hospitals, the class of servant termed "ward-maids," or scrubbers, should be employed. While the Committee recognise that the matron must be greatly responsible for the appointment and dismissal and general conduct of the nurses, they are strongly of opinion that no absolute power ought to be given to any matron, but that the appointments and dismissals should be made by the chief executive authority of the hospital. It is to be observed that many hospitals send out nurses after a certain period of training at sums varying from one guinea to three guineas a week to private patients. That these nurses bring considerable addition to the funds of the hospital there can be no doubt. The Committee consider that this is a good practice, but that, to prevent the wards from being denuded of nurses in order to bring funds to the hospital, a separate staff should be employed for this purpose. They are of opinion that the minimum period after which a nurse can be advertised as thoroughly trained is three years; and, considering the large amount of money these nurses can earn for the hospital, the Committee think that a sliding scale commission on their earnings, mentioned as being in practice at one of the large general hospitals, would be a fair addition to their regular hospital wages. Nursing in the Poor-law infirmaries differs in various institutions. In some a large proportion of nurses are hospital trained; but the Committee regret to find that one-half of the matrons are not regularly trained nurses. The Committee are strongly of opinion that not only all matrons, but that all nurses in a Poor-law infirmary should be trained nurses; the Committee would recommend that no nursing whatever should be done in infirmaries by paupers. The Committee consider that the number of nurses should be increased throughout the infirmaries and that infirmaries should train their own nurses.

#### PROPOSED CENTRAL BOARD.

This proposal has been already made public, but as it reappears in this report we quote it textually for the sake of giving completeness to our extracts:—

#### PROPOSED CENTRAL BOARD.

Various proposals for a central board are set out on pages I to III of this report. The Committee do not incline absolutely to any one of these proposals. They are of opinion that, as there is no Government grant, the interference of a Government officer for inspection would be unwise, and they think such interference would tend to check the flow of voluntary contributions and to some extent to interfere with the responsibility of the unpaid boards of managers. The Committee do not think that such a central board should be given any statutory powers as regards the formal licensing of any hospital built or about to be built. They would recommend that the proposed central board should be granted a charter to entitle it to receive endowments, legacies, bequests and contributions for distribution to medical charities and to meet its own necessary expenses. The board might be organised in the following way:—The various hospitals and dispensaries of all kinds should be grouped. The smaller hospitals should be grouped according to the classes of disease which they treat. Each general hospital, with or without a school, might be considered to be equivalent to a group. Each group would send one or more delegates to be members of the central board. The heads of the great medical corporations—e.g., the Royal Colleges of Physicians and Surgeons, the Medical Council and the Society of Apothecaries—might become members of this central board. The free and part-pay dispensaries might send one member and the provident dispensaries also one member. The Hospital Saturday and Sunday Funds might each send one member. A table is attached suggesting details for the formation of such a board. The duties of this board might be of the following nature:—1. It should receive annual reports, statements of accounts and balance-sheets from all hospitals and dispensaries, together with a return of the total number of in-patients, out-patients and casualty patients. 2. It should require that all accounts be audited by competent chartered accountants. 3. It should arrange that all medical charities should be visited and reported on periodically. 4. It should report from time to time, as occasion required, all proposals for new hospitals. 5. It should publish an annual report the principal heads of which might be as follows:—(a) A complete statement as to the pecuniary position of each medical charity. (b) A statement by a competent authority as to the existing sanitary condition and ventilation of each hospital, and as to arrangements concerted with the Metropolitan Fire

Brigade. (c) An account of the number of beds in use, the number of beds unoccupied, and the reasons why they are unoccupied. The average daily number of occupied beds, details as to beds for which payment is made, and the number of resident medical staff, resident officers, nurses and servants. (d) A statement as to the method according to which each hospital deals with its out-patients and casualty patients, and the number of each. (e) Proposals for the removal of hospitals and dispensaries to places where further hospital or dispensary accommodation is required, and the proposals for the establishment of new hospitals, and all other matters of interest relating to the treatment of the sick poor. (f) The nursing at hospitals and the proceedings of nursing associations in the metropolis. 6. The proposed board should early turn its attention to the possibility of so organising medical charities as to secure their cooperation with one another and the cooperation of medical charity with general charity.

## THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held at 36, Grosvenor-street, on Oct. 26th, 1892, Mr. George Pollock, President, in the chair. The meeting had been called to consider what resolutions should be proposed at the annual general meeting of the Fellows and Members on Nov. 3rd. The minutes of the last meeting having been read and confirmed, the hon. secretary reported that "the reply" drawn up at the last meeting had been revised and forwarded to the official of the College concerned therewith. It was agreed that this reply should be entered on the minutes. A letter was read from Mr. W. G. Dickinson, joint secretary of the Members' Association with Mr. Jabez Hogg, inquiring as to the action, if any, which the Association of Fellows intended to take at the general meeting of Fellows and Members on Nov. 3rd, and intimating a desire that the Members' Association should follow the lead of the Fellows' Association instead of taking independent action as heretofore. A long discussion ensued, and it was ultimately agreed to invite the support of the Members' Association to the following resolutions:—

1. "That this meeting of Fellows and Members desires to thank the Council of the College for acceding to their wishes in the matters (1) of separate meetings of Fellows and Members and (2) of the provision of a common room in the College."

2. "That this meeting of Fellows and Members wishes again to impress upon the Council that it is absolutely essential for the welfare of the College that the Fellows and Members should be consulted before any change is made in the constitution and external relations of the College, and before the College is committed to any extraordinary expenditure on buildings or otherwise."

The honorary secretary was directed to forward a copy of these resolutions to the honorary secretary of the Members Association. The meeting then adjourned.

## CHOLERA.

#### CURRENT NOTES, COMMENTS AND CRITICISM.

THE latest official statistics from Hamburg show that the recent epidemic of cholera there had resulted in 17,972 attacks and 7610 deaths. On Monday last it was announced for the first time for ten weeks that there had been no fresh case of cholera or death from that disease on the previous day. It is alleged that some of the cases previously reported had not on bacteriological investigation proved to be true cholera, and the authorities at Hamburg have decided to discontinue the daily publication of cases of choleric disease in future and limit it to such cases as are certified to be true cholera. The disease prevails to a slight extent in Holland, thirteen deaths from cholera being reported throughout that country last week. From Bruges we learn that a limited but sharp outbreak occurred in the commune of Coolkerke, West Flanders. There are a few fresh and fatal cases at Utrecht, Huissen, Ysselstein, Hendrik and Ambacht. At Budapest the disease continues, though not to any great extent, and a few cases, most of which terminated fatally, occurred at Tat in the county of Gran. The disease seems to have dis-

appeared at Vienna. Indeed, it is said that the cases which have occurred were only cholera nostras. The issue of daily bulletins from Vienna has been suspended, as no cholera now, at any rate, exists in that city. The authorities appear to have wisely made some preparations and arrangements in anticipation of any outbreak, and the Emperor Francis Joseph at the end of last week inspected the chief cholera barracks and expressed his satisfaction with that establishment, speaking at the same time in high terms of the services rendered by the Vienna medical students to that institution. The cholera returns for the month of October show that in Galicia 136 deaths were registered as due to the disease. In Bohemia one death only was recorded. An outbreak has occurred in Serbia, and the Bulgarian Government has established a military cordon along the Servo-Bulgarian frontier. Cholera does not appear to be prevalent in any part of Germany, and no bulletin was issued by the Berlin Sanitary Board on the 1st inst. At St. Petersburg the disease had not entirely disappeared, a few cases having occurred towards the end of last month. It is interesting to note that France has been modifying her views regarding a stringent quarantine system and considers that some of the measures imposed by Egypt and other countries are excessive and seriously injurious to the trade of Marseilles, the great French Mediterranean port. We are sincerely glad of this, for it is highly important that in all matters of public and international hygiene we should have the coöperation of a highly cultured, intelligent and scientific people like the French. The matters involved are those of public health and safety, and should be decided entirely on sanitary grounds and on the broad cosmopolitan principle of what is right and best for all, and separated from purely political considerations. No anxiety appears to exist on the Continent as to the epidemic prevalence or extension of cholera during the winter, although it is regarded as quite possible that the disease may not altogether die out. A certain amount of apprehension, however, very naturally exists as to the probable revitalisation and extension of cholera later on next year. Be this as it may, there are certain points and features connected with this epidemic that are both interesting and noteworthy. As regards the results of bacteriological examinations in most of these outbreaks of cholera, the earlier cases—those premonitory, as it were, to the outbreak—were alleged at the time to be only cholera nostras, in which unequivocal specimens of Koch's comma bacilli were either not present or only organisms of a closely allied morphological character were discovered; and towards the end of an outbreak of epidemic cholera, when the number of cases was rapidly tailing off, the same phenomena seem to have been observed. In the Paris epidemic, again, there was a circumscribed epidemic of the disease of apparently little or no infective intensity. It prevailed for a considerable time, showed little tendency—for some time at any rate—to spread, and yet, in point of fatality, was attended with a mortality quite equal to that of epidemic Asiatic cholera. That it was, in fact, true cholera seems undoubted, and is now universally admitted. But the French bacteriologists do not appear to have satisfied themselves that the organisms discovered during the whole course of the epidemic in the dejections of persons suffering from the disease were morphologically identical with those described by Koch after his investigations in Egypt and India; and some authorities in France have gone so far as to declare that the cholera which prevailed in the vicinity of Paris and the Seine had not been recently introduced, but was a product of the revitalised germs left by a previous epidemic which happened years before. It does not yet seem to have been definitely settled when the comma bacilli cease to be discoverable in the dejecta of a cholera patient. We seem now to have reached a stage in connexion with the relation of the comma bacillus to cholera in which it requires to be determined whether there are several comma-shaped organisms of closely allied morphological appearances developed in different diseases characterised by hyper-secretion of the intestine, and what is their relation to one another; and whether the predominant form is in any measure attributable or not to the nature of such secretion. The publication of the observations made by the bacteriologists of different countries where the disease has prevailed is awaited by all who are interested—and who are not?—in the scientific study of this disease.

As regards the port of London, we notice that on the 1st inst. the ship *Ossian* from Odessa was detained at Gravesend

and disinfected on account of having a case on board with suspicious symptoms of cholera. The patient was removed to the port sanitary hospital for treatment.

Whilst this cholera epidemic in Europe has been occupying our attention, it appears, according to advices from China, that an extensive outbreak of the disease had occurred in that country, notably at Cheng Ten, where the mortality has been something appalling. Up to Sept. 26th the number of deaths is alleged to have reached thirty or forty thousand.

## EPSOM COLLEGE.

WE have been asked to publish the following report of the School Committee of the Council of the College. It will be seen that, on the whole, the report is highly satisfactory:

The school committee have been carefully considering an exhaustive report from members of the school and finance committees, on the dietary supplied to the masters, pupils and servants of the College. A visit was recently paid without any notice being given to the College officials. The bread and butter are excellent. Good oatmeal porridge is supplied to the boys on alternate mornings. The tea is an excellent article supplied by a first-class London house. It is weighed—as is also the white sugar—and the milk measured when the tea is prepared for breakfast and tea. Unsweetened tea is supplied for those who prefer it. The diet table for fourteen consecutive days has been laid before us. The variety of the meat, and its mode of preparation, is satisfactory. The variety of vegetables is good, and the puddings daily supplied meet with our entire approval. The meat is boiled or roasted, of first-class quality, and stews or curries are given so that boys may have a choice of dishes not less than twice a week. The vegetables are good and well cooked, and comprise potatoes, cabbage, turnip-tops (carrots, turnips and onions in the stews), lettuces and beetroot. The puddings are given daily, and comprise raisin puddings, current dumplings, bread-and-butter puddings, rice pudding with jam, and suet-pudding with treacle or jam. Rhubarb is given in season, and cooked fruit as the markets permit. All these are carefully prepared and the masters partake of them at the same table as the boys at the mid-day meal. The provision of a first-class education with a good, wholesome, well-varied dietary strains the pecuniary resources of the College to the utmost. But the headmaster has advised the committee that a glass of milk in the early morning during the winter months would be of service. Your committee therefore recommend that half a pint of milk be supplied to each boy before he begins work. It is computed that this will cost about £30 per annum. In considering the question of supper no change for the present will be made. Beer has always been provided. It is good and wholesome. Luxuries we do not profess to give. The fees paid do not admit of it; and it is more than doubtful whether they are not harmful to growing lads. Delicate boys who need extra diet must pay for it, as in other schools. That the administration of the school in the past has been successful is proved—first, by the low rate of sickness, except when epidemic disease has been imported; secondly, by the reports of the examiners of the form work and by the successes of the boys who (going straight from the College) win distinctions at the universities, the hospitals and elsewhere, and enter the public services. This shows that the nerve forces of the boys are well nourished; and, lastly, but by no means least, the successes of the boys in the playing fields show beyond power of contradiction that their muscles are well nourished and well developed.

The authorities of the College are at all times willing to listen to any suggestions for the benefit of the pupils. It is hoped that parents will more frequently come and see how their sons are cared for. If this is impossible, written and signed communications will receive courteous attention in the future, as has always been the case in the past.

J. FAYRE, Chairman.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Derby Urban District.*—According to the census returns the Derby death-rates had to be considerably amended, but that for 1891 was not high—namely, 18.9 per 1000—compared with similar boroughs. The zymotic rate, which was 1.3 per 1000, was distinctly below the decennial average. Scarlet fever attacked 318 persons during the year, of whom 62 per cent. were removed to hospital, Derby having a new modern and attractive institution; and Mr. W. Iliffe speaks in high terms of the value of the building as a preventive against the spread of infection. In all, 398 cases of infectious disease were notified, and it is stated that no attempt at concealment took place, the system of notification having worked well. The infectious hospital was unable to meet all the demands made upon it, such is the result of the provision of a proper establishment. Evidently the erection of another pavilion is called for. Mr. Iliffe also recommends a building for convalescents. This involves a secondary question. If the 2000 cubic feet with

wall space &c. allotted to the beds at present are all occupied by acute cases, the results as regards recovery may turn out to be different from that which has hitherto been the case—a point deserving of consideration. The appendices to the report show that an efficient sanitary administration is efficiently maintained.

*Wolverhampton Urban District.*—Both measles and scarlet fever have been causes of anxiety in this borough, and a list is given in the annual report of cases where neglect, due to ignorance or intention, was the means of spreading the disease. A new pavilion at the hospital became necessary, and it was accordingly erected; and, as regards scarlet fever, Dr. Malet points out that in a number of instances the infection was apparently carried home by discharged patients, owing to the lack of proper means of bathing &c., before discharge. It is certain that such means can only be adequately provided by a separate building containing bath- and dressing-rooms, for if patients have to dress before discharge in the same building where infection exists it is impossible to say that they are incapable on discharge of conveying infection with them. But, whilst a discharge-room thus becomes necessary, we are convinced, as the result of considerable experience of which we have been made aware, that the essential cause of the apparent communication of scarlet fever by persons discharged as cured from scarlet-fever hospitals lies in the recrudescence of sore-throat in scarlet-fever patients and the absence of warning as to the results which are almost certain to ensue on such recrudescences. Wolverhampton had a death-rate of nearly 23 per 1000 during 1891.

*Dumfries County.*—Dr. Maxwell Ross, in presenting his first report on the sanitary condition of this county, sets out in considerable detail all those matters relating to topography, meteorology, population, dwelling accommodation, water supplies, streams, means of sewerage, industries &c. which are necessary to a proper apprehension of the conditions which have to be dealt with for public health purposes. The diseases which have prevailed in the constituent areas are discussed under separate headings, as are also the vital statistics. The report is, in short, a valuable work of reference with regard to all the circumstances affecting health, and with regard to mortality and other statistics up to current date, and will serve admirably as the introductory report to a series which we may hope will follow in succeeding years. With one point Dr. Ross deals separately in an appendix—namely, the subject of Hospital Accommodation, and it is quite evident that he attaches much importance to the necessity of providing means of isolation as a necessary supplement to compulsory notification of infectious diseases and as a necessary preliminary to disinfection of premises. He quotes much from the standard report on this subject issued by the English Local Government Board, and he sets out concisely the conditions under which the provision of means of isolation is likely to become a success on the one hand or a failure on the other. Dr. Ross apparently sees no reason for dealing with small-pox on such distinct lines as have appeared necessary to us; indeed he would evidently place his small-pox pavilion on the same site as that devoted to the ordinary infectious fevers. The explanation seems to lie in the fact that he apprehends the occurrence of but little small-pox; it is only thought likely to occur with comparative rarity and in small numbers. What the limit is as regards numbers in which there is danger of aerial diffusion of the infection we do not know; it probably varies much according to those unknown conditions which make one year favourable to the production of an epidemic and another unfavourable to it, that which is sometimes termed the epidemic influence. But until we understand what this involves, undue aggregations of small-pox cases should be avoided in proximity to dwellings or adjacent hospital buildings.

*Huddersfield Urban District.*—Dr. J. R. Kaye introduces into his annual report a "balloon view" of the borough, which gives an excellent indication of the topographical features of the district. Huddersfield had in 1890 the lowest zymotic rate of the twenty-eight large English towns, but last year it took a position nearly midway down the list; the general death-rate was also by no means low—namely, 22·9 per 1000; measles, influenza and whooping-cough being the chief factors in the increase of mortality. These three diseases are, so far as we can learn, only indirectly, if at all, affected by common insanitary conditions, and under these circumstances this increase is not one to cause anxiety. On the other hand, it must be a matter of gratification that the Birky Hospital continues to serve such excellent purposes. Thus no less than 325 cases of scarlet fever were under treat-

ment there during the year—namely, some 86 per cent. of the notified attacks. The hospital is in some respects by no means one of the best or most modern, and the result attained speaks well for its administration and for the growing public confidence in it. The influence of schools in spreading infectious diseases is described by Dr. Kaye, who lays down for the purposes of school teachers a few indications of the first symptoms of the diseases most commonly met with amongst scholars, so that they may be easily recognised in their earliest stages. Cellar dwellings seem to need considerable attention in Huddersfield, and the details given concerning them leave no doubt but that a number of them are, for obvious reasons, unfit for human habitation. Cowsheds, milkshops, bake-houses, slaughter-houses, common lodging-houses &c., all come in for comment as the result of the inspections to which they have been subjected. As regards slaughter-houses we should be glad to learn that in this and in all large towns none but public abattoirs were resorted to. But that day has hardly been reached by our sanitary authorities or by our legislators. Dr. Kaye's report, which is prepared not only for the immediate purposes of the current year, but as a permanent record intended to be of value for reference and other purposes, is an excellent type of what such a report should be. We are promised a further report on the survey of each of the districts into which the town is divided. This will carry with it a gradual house-to-house inspection, which must be regarded as one of the most useful of local sanitary measures—the one, in fact, on which intelligent measures of improvement can best be based.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5955 births and 3808 deaths were registered during the week ending Oct. 29th. The annual rate of mortality in these towns, which had been 17·3 and 18·0 per 1000 in the preceding two weeks, further rose to 19·5 last week. In London the rate was 18·5 per 1000, while it averaged 20·2 in the thirty-two provincial towns. The lowest rates in these towns were 12·3 in Croydon, 13·0 in Bolton, 13·3 in Sunderland, and 15·0 in Wolverhampton; the highest rates were 23·9 in Preston, 24·2 in Birkenhead, 25·2 in Hull, and 33·5 in Salford. The 3808 deaths included 406 which were referred to the principal zymotic diseases, against 389 and 387 in the preceding two weeks; of these, 96 resulted from measles, 82 from diphtheria, 78 from scarlet fever, 75 from diarrhoea, 37 from "fever" (principally enteric), 36 from whooping-cough, and 2 from small-pox. No fatal case of any of these diseases was recorded last week in Derby; in the other towns they caused the lowest death-rates in Blackburn, Sunderland, Burnley and Sheffield, and the highest rates in Oldham, Halifax, Brighton, Hull and Salford. The greatest mortality from measles occurred in West Ham, Oldham, Bradford, Hull, Brighton and Salford; from scarlet fever in Salford and Plymouth; from "fever" in Preston; and from diarrhoea in Wolverhampton, Oldham, Bolton, Hull and Gateshead. The mortality from whooping-cough showed no marked excess in any of the large towns. The 82 deaths from diphtheria included 56 in London, 4 in Halifax, and 3 in Birmingham. One fatal case of small-pox was registered in Halifax and one in Bradford, but not one in any other of the thirty-three large towns; 4 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 2 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 4012, against 3628, 3797 and 3936 on the preceding three Saturdays; 410 new cases were admitted during the week, against 503 and 484 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 267 in the preceding eight weeks, further rose last week to 296, but were 78 below the corrected average. The causes of 83, or 2·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Bolton, Preston, Sunderland, and in five other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Sheffield and Hull.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18.0 and 19.0 per 1000 in the preceding two weeks, further rose to 20.3 during the week ending Oct. 29th, and exceeded by 0.8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14.1 in Dundee and 14.5 in Paisley to 22.3 in Greenock and 22.5 in Glasgow. The 564 deaths in these towns included 43 which were referred to measles, 14 to scarlet fever, 12 to diphtheria, 10 to whooping-cough, 9 to diarrhoea, 2 to "fever," and not one to small-pox. In all, 80 deaths resulted from these principal zymotic diseases, against 75 and 87 in the preceding two weeks. These 80 deaths were equal to an annual rate of 3.2 per 1000, which exceeded by 1.2 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 12 to 39 in the preceding five weeks, further rose to 43 last week, of which 20 occurred in Edinburgh, 12 in Aberdeen, 6 in Glasgow and 5 in Leith. The deaths referred to scarlet fever, which had been 16 and 15 in the preceding two weeks, further declined to 14 last week, and included 10 in Glasgow and 3 in Edinburgh. The fatal cases of diphtheria, which had been 2 and 5 in the previous two weeks, further rose to 12 last week, of which 6 occurred in Glasgow and 4 in Edinburgh. The 10 deaths from whooping-cough corresponded with the number in the preceding week and included 7 in Glasgow. The 2 fatal cases of "fever" were fewer than those recorded in any recent week, and the deaths from diarrhoea also showed a decline. The deaths referred to diseases of the respiratory organs in these towns, which had been 82 and 97 in the preceding two weeks, further rose to 138 last week, but were 20 below the number in the corresponding week of last year. The causes of 55, or nearly 10 per cent., of the deaths in the eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20.7 and 19.4 per 1000 in the preceding two weeks, rose again to 25.8 during the week ending Oct. 29th. During the first four weeks of the current quarter the death-rate in the city averaged 21.5 per 1000, against 17.4 in London and 20.6 in Edinburgh. The 173 deaths in Dublin during the week under notice showed an increase of 43 upon the number in the preceding week, and included 6 which were referred to different forms of "fever," one to whooping-cough, one to diarrhoea, and not one either to small-pox, measles, scarlet fever or diphtheria. In all, 8 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.2 per 1000, the zymotic death-rate during the same period being 2.0 in London and 6.3 in Edinburgh. The fatal cases of "fever," which had been 4 and 2 in the preceding two weeks, rose to 6 last week, a higher number than has been recorded in any week since April last. The 173 deaths registered in Dublin last week included 28 of infants under one year of age and 39 of persons aged upwards of sixty years; the deaths of infants showed a further decline from those recorded in recent weeks, while those of elderly persons showed a further increase. Four inquest cases and 3 deaths from violence were registered; and 54, or nearly one-third, of the deaths occurred in public institutions. The causes of 13, or nearly 8 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

## MOVEMENTS OF MEDICAL STAFF.

HON. BRIGADE-SURGEON QUINLAN (retired pay) has been appointed to the Medical Charge at Galway. Surgeon-Major MacNeece and Surgeon-Captains Lendrum and Leishman have obtained leave on medical certificate from Bengal. Surgeon-Lieutenant-Colonel Quill has obtained sick leave from Bombay. Surgeon-Captain Moir has been transferred to Chatham for duty. Surgeon-Captain Shine has been transferred to Castlebar and Surgeon-Lieutenants Chambers and Lewis from Dover to Shornecliffe. Surgeon-Lieutenant Smythe has joined at Pirbright for duty with the Guards. Surgeon-Lieutenant Anderson has rejoined at Portsmouth.

## ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel George Wm. McNalty, M.D., F.R.C.S.I., has been placed on retired pay.

## INDIAN MEDICAL SERVICE.

The officers of the Medical Staff completing their tour of foreign service during the trooping season have sailed in the following troopships from Bombay:—*Crocodile*: Surgeon-Major W. L. Lane, Madras; Surgeon-Captain S. W. Hayman, Bombay; Surgeon-Captain M. L. Hearn, Madras.—*Scraps*: Surgeon-Lieutenant-Colonel W. F. Burnett, Bombay; Surgeon-Captain H. Carr, Bengal; Surgeon R. J. D. Hall, Bombay. *Euphrates*: Brigade-Surgeon-Lieutenant-Colonel G. J. Evatt, Bengal; Surgeon-Captain G. Cree, Bengal; Surgeon-Captain W. R. Crooke, Bengal.—Surgeon-Captain J. Crimmin, V.C., I.M.S., Civil Surgeon, Shikarpore, arrived at Bombay per s.s. *Malwa* on the 8th inst. Surgeon-Captain W. H. Bean, on arrival from England, will do duty in the Madras District, as will Surgeon-Lieutenant P. C. Gabbett; and Surgeon-Lieutenant J. L. Macrae, on arrival from England, will do duty in the Secunderabad District. Surgeon-Captain J. C. Addison, Medical Staff, on arrival from England, has been posted to Mhow District for general duty. Captain A. E. R. Tucker, 1st Battalion Cheshire Regiment, has been detailed for duty at the Regimental Depot in relief of Captain E. J. Lamb, who will complete his tour of such duty on March 1st, 1893. The following appointments have been made:—1st Bengal Cavalry: Surgeon-Captain G. T. Mould from the officiating to the Medical Charge of the regiment, with effect from August 4th, 1892. 20th Bengal Infantry: Surgeon-Major W. E. Griffiths from the medical charge of the 17th Bengal Cavalry, to the Medical Charge of the regiment. The above transfer is made solely in the interests of the public service. The appointment of Surgeon-Major W. E. Griffiths to the Medical Charge of the 19th Bengal Infantry has been cancelled. Brigade-Surgeon-Lieutenant-Colonel W. Grey and Surgeon-Captain S. T. Avelom, Indian Medical Service, have been permitted by Her Majesty's Secretary of State for India to return to duty. Surgeon-Captain T. D. C. Barry, F.R.S.E., F.C.S., F.I.C., Chemical Analyst to the Government, proceeded on special leave to Europe on the 6th ult. The services of Surgeon-Captain C. M. Moore, Indian Medical Service, are placed at the disposal of the Government of India in the Foreign Department. The temporary rank of Surgeon-Colonel has been conferred on Brigade-Surgeon-Lieutenant-Colonel S. B. Hunt, while officiating as Principal Medical Officer of the district in the Madras Command. Mr. Frank Bradley, Civil Surgeon, Lashio, has passed the Higher Standard Examination in Burmese, and is the first medical officer in the Burma Service to attain this literary linguistic distinction.

## NAVAL MEDICAL SERVICE.

Surgeon William Hayes has been placed on the Retired List. VOLUNTEER CORPS.

*Rifle*: 3rd Volunteer Battalion, the East Surrey Regiment: Surgeon-Captain J. E. Lane, M.D., has resigned his commission.

## RECOGNITION OF MERIT.

Lieutenant Geo. F. McMunn, R.A., the son of the principal medical officer of the Chelsea Royal Hospital, Dr. J. Alexander McMunn, has been appointed a Companion of the Distinguished Service Order in recognition of his services in connexion with the recent operations in the defence of Sadon.

## THE ISAZAI FIELD FORCE.

We recently called attention to the announcement that no field hospitals had been provided for this force on taking the field, but were in doubt as to the accuracy of the report, for it did not appear clear how the sick and wounded soldiers were to be treated without hospitals of some kind. We find from our contemporary, the *Indian Medical Gazette*, however, that, as a matter of fact, no field hospitals were provided for the force. Corps were supplied with full marching scale of establishment, ambulance transport, and camp equipment. As it happened, Sir William Lockhart's force advanced and captured an unoccupied post, and the force promptly returned to their quarters. Had the circumstances been different, and had the force been detained in the hills and actually engaged in any warfare, we confess that we do not understand how the sick and wounded would have been adequately accommodated and provided for.

A correspondent, writing from Camp Palosi to one of the Allahabad papers on Oct. 7th, regarding the occupation of Baio, while highly praising the work done by Surgeon-Colonel Harvey and the medical officers of the expedition, alludes to the insufficient number of medical officers provided for the work and to the late arrival of stores of various kinds, which he attributes to the economical desires of the authorities. He mentions the fact of an outbreak of cholera—

fortunately of a comparatively mild kind—having occurred (forty cases and fifteen deaths), and alludes to the difficulties that must have arisen had a big action taken place at Baio.

#### THE NEW RIFLE AND MEDICAL SERVICE REQUIREMENTS.

In the last number of the *Journal of the United Service Institution of India* Captain Cox discusses the subject of the probable changes that will be brought about in warfare by the introduction of the new magazine rifle. The main points in the superiority of the new weapon introduced into the British army are increased range, greater flatness of trajectory, increased penetration and greater rapidity of fire with an absence of recoil. The tactical effects that will follow the introduction of the new rifle do not concern us. The nature of the wounds and the number of the wounded are, however, matters of interest to the medical services. Captain Cox arrives at conclusions in these respects which do not materially differ from those of other authorities and writers on the subject—viz., that the number of casualties from comparatively slight wounds will be largely increased, calling for additional field hospitals and bearer columns to succour and provide for the increased number of wounded, and this will tend to diminish the mobility of an army. It is argued that, as far as field armies are concerned, wars will be decided more rapidly in future. The armies of all nations are supplied more or less with new arms of precision of some kind. As regards the French in Dahomey, we are still without any precise official details of their experience with the Lebel rifle.

#### THE LATE CYCLONE IN MAURITIUS.

We are glad to notice that the medical service is included in the general order published by the officer commanding the troops in the Mauritius notifying his Royal Highness the Commander-in-Chief's very great satisfaction at the admirable conduct of the force and the important services rendered by the garrison of Port Louis on the occasion of the late cyclone. It appears that a despatch from the Acting Governor of Mauritius to the Secretary of State for the Colonies had called attention to the subject. Among the names of many officers, non-commissioned officers and men who are honourably mentioned, those of the following medical officers occur: Brigade-Surgeon-Lieutenant-Colonel Maunsell, Surgeon-Captain McCulloch and Surgeon-Captain Luther, Medical Staff.

#### CHOLERA MORTALITY IN INDIA.

Our contemporary the *Indian Medical Record* for October last, quoting from a cholera table, shows a terrible record of deaths from that disease. In fourteen years, from 1877 to 1890, it declares that 1,000,826 persons have died in Bengal from cholera alone.

#### THE MILITARY FORCES OF EUROPE.

So large are the forces existing at present that Europe may well be styled an armed camp; but taking the figures recently published by the *Cologne Gazette* these forces will become enormous in the near future and altogether disproportionate to any medical service that can be organised, even if we make every allowance for very large additions from the volunteer services and civil medical element of the different nations concerned. According to the extended conscription at present in force the army in France on a peace footing numbers 519,000 men, and she will have in twenty-five years 4,053,000 trained men; in Russia the peace establishment, excluding the army in Asia, is 887,000, and in twenty-three years her army will be approaching 5,000,000. Germany now proposes to recruit for a two years' service and absorb every really able-bodied man, and in that way to raise her army in peace to 492,000 men, exclusive of officers, and it is estimated that she will have at her disposal between 4,000,000 and 5,000,000 of drilled men in twenty-five years' time. It is perfectly clear that only portions of such enormous forces can take the field at a time, for it would be impossible to feed them, to say nothing of providing them with the necessary medical and surgical aid. It can presumably only be intended to put a certain number of army corps in the field and follow them up by others during a campaign. It is a ghastly outlook at present, but twenty-five years is a long time, and the system under which these colossal armies are possible may have altogether broken up in the interval.

#### REGIMENTAL INSTITUTIONS.

Lord Roberts has been instrumental in starting in India a system of regimental institutions, after the nature of a club,

for the use of the soldiers of corps serving in that country, which, according to a correspondent in the *Army and Navy Gazette*, are said to work well in increasing the comfort and well-being of soldiers and in developing habits of sobriety and good order amongst them. The old system of dingy and uncomfortable barrack canteens is stated to be very inferior to that of the newer regimental institutions. Marked and progressive improvements have taken place of late years in all that concerns the social and sanitary conditions of the soldier in India.

## Correspondence.

"Audi alteram partem."

### "ANNUAL GENERAL MEETING OF FELLOWS AND MEMBERS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—In your annotation of Oct. 29th, under the above heading, you "strongly urge all Fellows and Members who have the good government of the College at heart to attend the meeting on the 3rd and support the resolutions which will then be submitted." It seems to me that not a few Fellows and Members who have the good government of the College at heart will absent themselves from the meeting on the 3rd for the following reasons: 1. Their presence at their own College can at present only carry with it the value of protest; this protestation has already been frequently expressed. 2. Their views on just reform can be promoted, for the time being, with great force and cogency, outside the College; and the drafting of suitable men into the Council in July has far more real significance than a full attendance at the annual meeting in November. 3. The calling together of Fellows and Members indiscriminately—men engaged in an arduous profession—to listen to, maybe to speak on, a bald annual report, yet utterly and absolutely unable to amend or alter it in any respect, is an insult to the Members and a greater stultification of the Fellows.

When, in due course of time, the Members of the College are fairly recognised and Fellows have an authoritative vote on the proceedings of Council, then will be the opportunity for both Fellows and Members to re-enter and prove that criticism need not imply a lack of goodwill nor independence of thought disloyalty to their College.

I am, Sirs, yours faithfully,

Welbeck-street, W., Oct. 31st, 1892.

RICHARD DAVY.

### PAYMENT TO MEDICAL OFFICERS OF WORKHOUSES.

To the Editors of THE LANCET.

SIRS,—I have just received intimation from the London County Council that they are prepared in future to sanction the payment of medical officers of workhouse infirmaries for giving evidence at the coroners' court and for making post-mortem examinations. This decision has been arrived at upon the opinion of Mr. Poland, Q.C., who has recently been consulted on the matter. It does not necessarily follow that other county councils will take the same view as that which is now adopted by the London County Council, as coroners generally have been guided hitherto by the case of *Don Bavaud v. Morrison*, which was heard before his honour Judge Lushington at the Croydon County Court in 1885, and decided adversely to the interests of infirmary medical officers. It is to be hoped that Mr. Poland's opinion will, however, guide coroners and county councils generally, so that they may come to the same decision as that arrived at by the London County Council. A full copy of Mr. Poland's opinion could doubtless be obtained if required on application to the chief officer, Public Control Department, 21, Whitehall-place, S.W.

I am, Sirs, yours truly,

St. Mary's-terrace, W., Nov. 1st, 1892.

G. DANFORD THOMAS,  
Coroner for London.

## "EXPERIMENTS ON ANIMALS."

To the Editors of THE LANCET.

SIRS,—Dr. Clarke, in his letter upon the above subject, agrees with Dr. Tyson in his appeal for facts in support of vivisection. I shall be glad if you will allow me a short space in your columns to mention some facts connected with operations performed on the stomach and intestines which may, I think, go far towards convincing the sceptical of the utility of experiments on animals in this department of surgery. In the year 1889 I conducted my first series of experiments based upon those described by Professor Senn. I again in 1891 carried out a second series. Details of these experiments have been described in the medical journals and at the medical societies, and the subject is fully treated in my work entitled "Surgical Diseases of the Stomach and Intestines." Until the year 1890 there had not been one successful case of pylorotomy for carcinoma reported in this country. The details of five cases had been published, all of which had been unsuccessful, the patients dying within eighteen hours of the operation. In 1890 Mr. Rawden reported a case of pylorotomy in which he had united the divided ends of the stomach and duodenum by means of decalcified bone-plate. This patient made a good recovery and returned to his work. In July, 1891, I performed the combined operation of pylorotomy and gastro-enterostomy on a woman for carcinoma of the pylorus. This patient is alive and well fifteen months after the operation. She has gained 56 lb. in weight and follows her usual employment. I can only find two recorded cases of gastro-enterostomy reported before the year 1890—one of these recovered and one died eleven days after the operation from exhaustion due to incessant vomiting. Since the publication of the results obtained by experiments on animals gastro-enterostomy has been performed a considerable number of times. I have before me the results of twenty-four cases, of which seventeen made good recoveries. Some of these patients have been operated upon for over two years and are still alive and able to enjoy life. Besides these, a large number of cases of intestinal anastomoses have been performed successfully for the cure of fæcal fistula, gangrene of the intestine due to constriction of the gut in strangulated hernia &c. I venture to assert that these good effects were the direct result of experiments performed on animals, a success which would not have been obtained if the operations and experiments had not been carried out. In other departments in surgery equally great advances have been made by experimental research; but of these I will leave others to speak.

I am, Sirs, yours faithfully,

FRED. BOWREMAN JESSETT.

Buckingham Palace Mansions, S.W., Oct. 30th, 1892.

To the Editors of THE LANCET.

SIRS,—The letter of Dr. W. F. Clarke in your last issue indicates the true source of much of the bitterness of the anti-vivisection controversy. The opponents of the practice of vivisection, as Dr. Clarke points out, are not met fairly. While its defenders declare that everything is done under anaesthetics—that if the animals feel any pain it is no worse than the prick of a needle; that every important discovery in medicine, surgery and pharmacology has been made in consequence of it; that its opponents are mere sentimentalists; and so forth—your dispassionate readers, like Dr. Clarke, cannot be surprised that we devote our whole energies to protest against such want of candour on the part of men who cannot use such arguments without some sense of degradation. Hermann of Zurich and Dr. Charles Richet own honestly that they work for science and science only, without bothering their heads about the progress of the healing art or the good of humanity. If English scientists would get rid of this cant some of those who now fight because of their English love of fair play would be able to acknowledge that the defenders of experiments on animals had the courage of their convictions and were not sailing under false colours. While we are treated as a pack of "shrinking sentimentalists" and mere lap-dog philanthropists we feel that we do not receive the justice our cause demands. Meet us fairly and it will be found that we are not quite the sort of people we are supposed to be by some of our opponents.

I am, Sirs, yours truly,

EDWARD BERDOE, L.R.C.P. Edin., M.R.C.S.

Victoria-park, N.E., Oct. 20th, 1892.

## HYPNOTISM DURING AN OPHTHALMIC EXAMINATION.

To the Editors of THE LANCET.

SIRS,—I shall be glad if you can find space to publish the following brief notes of a very remarkable case which has recently come under my notice, in which hypnotism was induced during an ophthalmic examination. I have searched all the literature which is at my command and can find no record of any similar occurrence, and shall be glad to learn from any of your readers if any similar cases have been recorded. A woman, aged thirty-six, was admitted on Oct. 22nd into the Northumberland, Durham and Newcastle Infirmary for Diseases of the Eye, under my care, suffering from optic atrophy. She is a very broken-down-looking woman, and, without giving her symptoms in unnecessary detail, I may say that I came to the conclusion that she was in an early stage of general paralysis. Her memory is defective. She does not speak well, clips words, and sometimes misuses them, and probably has some delusions. Her pupils are widely dilated, do not react to light, and in certain directions there is nystagmus. She has occasional bad headaches and her patellar reflexes are much exaggerated. Both discs are very white, and it is doubtful if she can see light. The day after she was admitted she was taken into the dark room for ophthalmoscopic examination. Whilst examining her I observed to the lady superintendent who was present that the patient seemed drowsy, and it occurred to me that she was becoming hypnotised. I left off the examination and making a few passes over her face with my hands I soon found she had passed into a condition of deep sleep. Continuing to make passes with one hand, with the other I raised her left arm at right angles to her body, and subsequently the left. They both remained rigidly in the same posture as that in which they were placed. It was now noticed that both eyes were not equally closed and that there was an evident ptosis in the left eye and partial paralysis of the left side of the face, the mouth being drawn to the right. I now shook the patient and called her loudly, when she gave a deep sigh and woke up. The ptosis and facial paralysis remained marked for a few moments and then disappeared, or at all events became so slight that I should never have noticed it had I not known it existed in a latent form. On asking the patient when she awoke what she had been doing she said that she had had a pleasant sleep and that a headache she had previously disappeared during the time. I suppose this patient, probably owing to cerebral disease, is specially susceptible to hypnotic influences, for I have found that I can always reproduce the same phenomena at pleasure, and have done so before several medical men; but the most interesting feature in the case is that during the hypnotic state certain symptoms should develop which are unnoticeable under ordinary circumstances. The hypnosis here, so to speak, enables the nervous system to cast in advance a shadow of symptoms which the real disease will almost certainly develop at a later period.

I hope some of your readers who are conversant with hypnotic phenomena will say if the same phenomena have been observed in other cases—that is, if patients have exhibited whilst in this condition symptoms of nervous or other derangements which have subsequently become realities, because if this is so hypnosis may occasionally become a valuable adjunct in diagnosis and prognosis. I may say this woman is quite uneducated—I should think has at all times had an intellectual development below the average, and has never heard of mesmerism or any of its methods. She thinks nothing of the phenomena, but tells the other patients that the doctor can put her to sleep.—I am, Sirs, yours faithfully,

C. S. JEAFFERSON, M.D. St. And., F.R.C.S. Edin.

Newcastle-on-Tyne, Oct. 30th, 1892.

## "ACUTE INFECTIOUS EPIPHYSITIS."

To the Editors of THE LANCET.

SIRS,—In the annotation on Drs. W. M. Coplin and D. Bevan's paper on the above subject in the *Philadelphia Medical News* of Aug. 13th you mention certain conclusions at which they have arrived and certain opinions with which they are in accord. Permit me to mention that in my paper in the *Guy's Hospital Reports*, 1890, on this disease I drew the following conclusions:—1. The disease is due to the irritation and suppuration occasioned by the entrance and

development of the staphylococcus pyogenes aureus, and that it is a specific disease and not merely traumatic periostitis which gives rise to death of the shaft. 2. The earliest symptoms appear in the juxta-epiphyseal regions and spread thence inwards to the medulla and outwards to the periosteum, assisted by the continuity of the latter with the epiphyseal cartilage. To prove this point I made a series of experiments on young rabbits, and in the article in question full details are given. 3. In cases of total death of the diaphysis the destructive process is most marked at the extremities, the bone here being found eroded and gangrenous; and further that there is such a loss that the dead shaft no longer fits accurately into the epiphyseal and periosteal cap. You also remark that amputation seems to be the only treatment. With this I cannot agree, as the conclusion I came to was that operators must not merely be content with incising the periosteum and letting out the pus, but should attack the disease immediately at its root by tunnelling the juxta-epiphyseal junction in addition, and so allow a sufficient exit for the products of the inflamed medulla.—I am, Sirs, yours faithfully,

A. H. TUBBY, M.S. Lond., F.R.C.S. Eng.  
Finsbury-circus, E.C., Nov. 1st, 1892.

### "ANALYSIS OF 10,000 CASES OF DISEASE AND DISTURBANCE OF THE EYES."

To the Editors of THE LANCET.

SIRS,—The two instructive instances of unsuspected foreign bodies in the eye related by Mr. Brudenell Carter in his most interesting and practical article in THE LANCET of Oct. 29th recall to my mind one which was perilously near bringing me to unmitigated grief. A nervous young man came to consult me about "something in his eye." I examined him carefully but could detect nothing save violent purulent inflammation of the conjunctiva, and I told him so. It transpired that he had already consulted two medical men in London (where he lives) and that they both considered he was suffering from gonorrhœal ophthalmia, a diagnosis in which I was disposed entirely to agree, especially as I found he had still a troublesome gleet. I prescribed a lotion of boric acid and alum—being antiseptic to the backbone—which he seemed to think "dear at the price." My patient was going away, in no very amiable mood, when he turned at the door and said, "I know there's something in it!" "Come back, then, and let me have one more look." I seated him again in a good light, and, with the aid of a powerful pair of glasses (alas, presbyopic!), I was fortunate to discover, by the merest chance, a round black point almost hidden by a loose fold of mucous membrane, which had doubtless concealed it during the previous examinations. With a pointed pair of forceps I had no difficulty in extracting a long, round, sharp, black thorn quite half an inch in length and as thick at one end as a silver probe, which had been embedded in the loose tissue at the external angle of the eye and quite clear of the globe. When pressed for an explanation of its presence he told me that some three weeks previously he had scrambled through a hedge and a twig had struck the eye, but did not hurt it. As he left the consulting-room he muttered irrefully, "What jolly fools doctors are!" Grateful!—Let me take this opportunity of adding my humble testimony to that of Mr. Brudenell Carter as to the efficacy of solution of nitrate of silver and the inefficacy of soothing antiseptic washes in the treatment of ophthalmia neonatorum. This was, of course, the universally received teaching in my young days, but the rising generation are nothing if not germicidal. Without at all undervaluing antiseptics it sometimes, I confess, occurs to me that the almighty microbe is getting just a trifle too rampant and requires a little judicious "sitting on."

I am, Sirs, yours truly,  
CHAS. EGBERTON FITZGERALD, M.D. St. And.  
Folkestone, Oct. 20th, 1892.

### CHLORIDE OF ETHYL: A WARNING.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of this week, under "New Inventions," Dr. Bengué's instrument for the administration of chloride of ethyl is spoken of in connexion with dental as well as other minor surgical operations. I write this note as a warning, as I believe the inhalation of the vapour is not

altogether free from danger. Having occasion to scarify a small patch of lupus erythematosus on the nose of a young lady, I thought it a favourable opportunity to try a chloride of ethyl tube. The spot was frozen well enough, but the patient turned pale, slightly livid and stopped breathing, looking very like a person under nitrous oxide gas. As I took away the ethyl at once she recovered in a few seconds, but I should certainly not use it again to any part of the face where it was possible that the vapour could be inhaled. Chloride of methyl applied by means of a tampon is far safer and easier, but care must be taken not to over-freeze the skin or a dermatitis may be set up.

I am, Sirs, yours faithfully,  
Harley-street, W., Nov. 1st, 1892. H. RADCLIFFE CROCKER.

### "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—In the elucidation of this subject a specific instance of the working of one of these institutions is worth more than a great deal of generalisation. Having been medical officer for five years, from its inception, to one of these associations, I am in a position to supply you and your readers with some particulars which may prove interesting. The Walsall Medical Aid Association was formed in 1885, and I was appointed its first surgeon at a salary of £180 a year, to be raised to £200 as soon as it was found to be a success. This was soon demonstrated, and in the course of twelve months or so the promise of a rise in my salary was fulfilled. By 1887 the Association had close on double the number of members it had at the beginning, and I thought I might now seek for a rise in salary. I may explain that, in addition to the fixed salary of £200 per annum, I had a house free, midwifery fees at 12s. 6d. each, with vaccination and teeth extraction. The midwifery cases did not quite average one a week. I was allowed one shilling a week from the committee, or paid that amount for the heating and lighting of the surgery, waiting- and consulting-rooms, while I had to pay the coal and gas account of the whole establishment—my house and the surgery &c. being in the same building. When, then, the members had increased so much as to be nearly double, I applied (1887) to the committee for a little relief, which would be tantamount to a small rise in salary—viz., for them to take over and pay from their own account and thus relieve me of the coal and gas account of the whole establishment. I was refused and told that they regarded my position as very superior and that I ought to be content. I was then not in a position, by any means, to defy them, so I was forced to work away for over two years more, till 1889, until the members increased to close on 4500, at the original fixed salary of £200, while all this time a handsome balance to the good was seen to be realised. Was I not, under these circumstances, entitled to a rise? What did they want with the surplus; and by whose exertions was it earned? Fancy a surgeon to this association, that began with 1800 members and now had increased to 4500 or thereabout, only having the same salary for attending to the latter number as he had for attending the former! What can this be called but "sweating"? Furthermore, when the dispenser, who was having £60 a year, asked for a rise with an increase in his work he was refused and a junior qualified surgeon obtained in his stead, at a salary of £100 out-door, who, however, only remained a few months, as he could not get an adequate increase to induce him to stay; and when he was first appointed it was said to me that the management expected that now I had assistance in visiting I should be able to save in cab hire what it took to pay the junior surgeon over the former dispenser. What was all this?—only an attempt to "sweat" the surgeons for the benefit of the estate of the association. The annual report of the year I left (1890) shows that for each member the surgeon was paid on an average 10½d., while each adult paid 3s. 6d. and each juvenile 2s. per annum. A quarter's contribution from each member went to pay the medical attendance, which is the primary object of these institutions, while the remaining three-quarters' contributions went for extraneous business, a large part of which, no doubt, was expected to be profit at the year's end out of the toil and labour and "sweat" of the unfortunate surgeon. Such has been the working of the Walsall Medical Aid Association from July 1st, 1885, until May 1st, 1890, while I was their medical officer. They had several changes after I left—two or three in the course of a

few months. This reduced their surplus funds, it appears, showing how much of the success—I should say 99 per cent. of it—is due to the medical officer, who is made also a profit accumulator for the institution. I presume this is only a type of many other of these combinations.

I am, Sirs, yours faithfully,  
D. RIORDAN, M.D. Q.U.I., M.R.C.S.,  
First Surgeon to Walsall Association.

Oct. 25th, 1892.

*To the Editors of THE LANCET*

SIRS,—I should like to say a few words in connexion with the above subject and the letters which appeared in your last issue. Your correspondent "Verax," though he appears to write with a strong bias, is certainly right in some of his points, though wrong in others. He is right in what he says of the wretched pay given to their assistants by the majority of medical men. In my opinion it is nothing less than scandalous that a fully qualified man should have to accept and work harder for it than a mechanic, the miserable pittance usually offered, with the risk of being discharged at any moment of caprice, after perhaps years of service and often worse treatment than any domestic. But this will never be remedied until it is made illegal to employ unqualified assistants at all. "General Practitioner" says a qualified man cannot and will not do the drudgery an unqualified man will. He can and will. His argument that a qualified man is not necessary for club patients because the majority have only fancied ailments will not hold water; for though it is weary work sifting the corn from the chaff the real illness is there, and it requires a man well conversant with disease, and often a good one, to recognise it among the mass of trivialities. It is very much the fault of medical practitioners generally that Medical Aid Associations are able to go on; for if they would keep only qualified assistants and pay and treat them well, the associations would find difficulty in securing officers or members. I am now neither an assistant nor do I keep one, nor am I a resident medical officer to an association; but I was an assistant for a short time, and, though I was fortunate in my principal, my experience of the discourtesy of very many men and the poor pay they offered when I was looking for an appointment thoroughly disgusted me with them, and I do not wonder at men preferring to work for an association. "Verax" is, however, wrong in defending the associations, in accepting as patients those who can afford a fair fee. He asks if there is a case on record of one medical man refusing to take a patient from another at a lower fee. Yes, certainly; myself and many of my medical friends do so constantly if the patient can afford what he paid his previous attendant. Many of us, unfortunately, do undersell; but it is an indefensible practice for a regular practitioner—still more so for an association whose sole *raison d'être* is as a charitable institution and not as a financial concern. As such they should be tabooed by the profession. As to the association returning pence to their members, it is very kind of them; but why not have added them to the officer's salary as a bonus? If the associations would confine themselves to those who can but afford the halfpenny or penny a week, I can see no reason against them, but when they accept patients in a better position, then they go out of their sphere and become piratical. Apologising for the length of this letter,

I am, Sirs, yours sincerely,  
FAIRPLAY.

Oct. 25th, 1892.

*To the Editors of THE LANCET.*

SIRS,—As medical officer to one of the best conducted medical associations I consider the statements made by "Verax" to be no defence whatever, and in fact quite outside the question. First, as to the position held by the medical officer. He is the *paid servant* of some person or persons not connected in any way with the medical profession. This is a most undignified and indefensible position. Now "Verax" states "the scanty allowance" he receives is more than he could make in private practice. Then, if this is correct, "Verax" is not, on the face of it, entitled to what he now receives or what he received when an assistant; for if he is not competent to maintain a private practice, he is not competent to hold the post of medical officer to one of these associations, for of necessity the work must be far greater than ordinary private practice, and I am in a position to prove it. Then, again, the assistant to a general practitioner is quite different from the position of a medical officer to an association. In the

case of the assistant he is under the control and guidance of the principal, and does actually assist a legally qualified surgeon; whereas the medical officer to an association is the actual principal, does the whole of the work, allows a trading company to absorb the profits, and in return receives very little more pay than he would receive as assistant to a surgeon. As to the midwifery fee, that should be an arrangement between principal and assistant, and bears no relation to the question of attending members of an association for a fee of 10s. 6d. and handing 3s. 6d. out of this sum to the association for the honour of attending the confinement. Then, again, when an assistant or locum tenens carries on a practice until it is sold it is quite outside the question, and, besides, is only temporary. I do not think any association would be actuated "by the thought that by dismissing a medical officer they would thereby throw him on the tender mercies of his fellows," when I can instance one association that has had thirteen medical officers in three years! It certainly is systematic robbery for an association to purchase property out of money earned by medical and surgical work. With every confidence I appeal to the General Medical Council to consider the interest and welfare not only of the medical profession but also of the public, who in "sweating" medical men will find the iniquitous system rebound on themselves.

I am, Sirs, yours faithfully,

Oct. 22nd, 1892.

L.R.C.P.LOND.

AMPUTATION FOR DIABETIC GANGRENE.

*To the Editors of THE LANCET.*

SIRS,—I have read with much interest the report of Mr. R. J. Godlee's paper on the above subject. In it he points out that the so-called diabetic gangrene is in most cases dependent upon one of two causes—i.e., atheroma of the vessels or peripheral neuritis. Whilst accepting this statement, I would at the same time venture to draw attention to a type of diabetic gangrene in which both these conditions—atheroma and peripheral neuritis—are present. The recognition of this class of case is, I believe, of considerable value, since we have here to deal with two important causative factors. Amputation in such cases would, I apprehend, be attended by much less beneficial results than in those in which the disease was due to one only of the two causes. I have met with this form of gangrene in three patients, all of whom died. The post-mortem examination in two revealed extensive atheroma of the posterior tibial vessels. The posterior tibial nerves were also found to be the seat of well marked neuritis. This lesion was likewise present, although to a lesser extent, in the sciatic nerve in one case. I believe that amputation would only have accelerated death in these patients.

I am, Sirs, yours truly,

T. DAVIES PRYOE,

Oct. 30th, 1892.

Hon. Surgeon, Nottingham General Infirmary.

"MR. BRAXTON HICKS ON UNQUALIFIED ASSISTANTS."

*To the Editors of THE LANCET.*

SIRS,—The remarks on the case of Robert Barnet in THE LANCET of Oct. 29th are not quite consistent with the facts, and you will doubtless in justice permit me to modify your statements. My surgery, a very short distance from my father's residence, is entirely under my supervision, the visiting and prescribing being done by myself—my assistant, who has passed his hospital curriculum and has had many years' experience, being employed in dispensing, attending midwifery and visiting only in my occasional unavoidable absence. In the particular matter in question the assistant responded to an urgent call, and I saw the patient immediately afterwards. It is entirely untrue that brandy was suggested or given by the assistant, but he ascertained that the relatives had previously to his arrival endeavoured to administer the stimulant to the unconscious man.

I am, Sirs, yours truly,

Upper Kennington-lane, S.E., Oct. 31st, 1892. ROBERT GRAHAM.

THE gold medal for the best essay presented at the University of Durham examinations during the year 1891-92 for the M.D. degree has been awarded to Dr. J. F. Johns, of the London Hospital.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*The Medical Defence Union.*

A LOCAL branch of the Medical Defence Union has been formed here. The committee has been well selected, and the names of the gentlemen composing it will command the respect of all concerned. In past years many local practitioners have had to defend actions which ought never to have been brought against them and which probably never would have been had they at once placed their cases in competent hands and assumed a firm attitude. The local defence union deserves, as it will no doubt receive, very hearty support.

*American Doctors.*

For some time the local papers contained most extraordinary advertisements of American doctors, who were apparently carrying everything before them. After a while the advertisements ceased and one of these "doctors" appeared before the local stipendiary magistrate on a charge of obtaining money by false pretences. The case has been remanded and it is expected that another "doctor" will be charged next week. Any comment would therefore be improper, but it may be stated that the magistrate has expressed his intention to send the case to the Assizes and that he has refused bail.

Liverpool, Nov. 2nd.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

*Newcastle Hospital Sunday Fund.*

ON Sunday last the annual collection was made in the churches and chapels of the city for our medical charities. The day was exceptionally fine for the time of the year, so that no one was prevented from going to a place of worship owing to the weather. It is to be hoped, therefore, that there will be no falling off from the previous high record. It is the collections at the factories which give the most concern. These are to be made on the 14th inst., under rather unfavourable auspices. For instance, the long strikes in the spring, and also the fact that the men when they did return to work in most cases went in at reduced wages, must be remembered.

*Gift to Sheffield by Mr. B. Bainbridge.*

Mr. Emerson Bainbridge, well known in Sheffield in connexion with all philanthropic movements (and whose family in Newcastle is equally known in the same paths), has announced his intention of making a further munificent gift to the town of Sheffield. He proposes to purchase from the Corporation a plot of land near the municipal buildings and to erect thereon a building to serve the purposes of a children's refuge, where all waifs and strays of the town may be sure of shelter, warmth and food. He hopes the Society for the Prevention of Cruelty to Children will take over the building and so, while alleviating the present distress, provide for the future of the children.

*Rabies at Scarborough.*

It is reported that there is a rather serious outbreak of rabies at Scarborough. The muzzling order is in force and more than a score of dogs have been destroyed.

*The MacLagan Fund at Berwick.*

A largely attended meeting of subscribers to this fund was held on Monday night last at Berwick, under the presidency of the Mayor. It was agreed that the permanent public memorial to the late Philip Whiteside MacLagan, M.D., should take the form of a statue of Hygeia and drinking fountain, with medallion of the late doctor and suitable inscription, to be erected in the High-street, Berwick. The remainder of the money, about £600, is to be handed over to the daughters of the late Dr. MacLagan.

*Odds and Ends.*

An explosion of hydrogen gas took place last week at Penrith during a chemistry lecture in connexion with the course started by the Technical Education Committee. The explosion is described as being rather serious, injuring some of the pupils slightly, while the lecturer was so scorched and blinded that he will be unable to resume his duties for about

a week.—Mr. Bindloss of Kendal, at a late special meeting of the Corporation of that town, made an offer on behalf of himself and wife to build a new town-hall to be opened on the occasion of their silver wedding in 1894. The cost of the structure will be about £10,000. The present building was shown to be inadequate for the required accommodation for magistrates, police &c., and was of course open to sanitary objections. This generous offer of Mr. Bindloss was duly accepted by the town with thanks.—An unpleasant visitor arrived last week in Carlisle in the form of a tramp with small-pox. It was shown that his journey to the border city was (from Huddersfield, where small-pox existed) by Pateley-bridge, York and Newcastle. He also visited several places the names of which are not known.—Lady Mary Fitzwilliam has been holding a very successful bazaar in Doncaster in aid of ambulance work.—The Mayoress of Hartlepool distributed the certificates and medallions to the large class which had been instructed by Dr. B. Morison. In the report it was stated that 160 students had attended the first-aid ambulance class.—A handsome drinking fountain has been erected near the central station in this city in memory of Richard Grainger, the builder of modern Newcastle.

*The Railway Collision near Thirsk.*

In reference to the dreadful railway accident which happened this morning, it would appear that at least nine lives have been lost. A great number of persons who have been injured have reached their destinations and so are scattered about the country. Mr. Hartley, surgeon to the North-Eastern Railway at Thirsk, informs me that he has two passengers at the Thirsk Hospital suffering from great shock.

Dr. George M. Murray has commenced a post-graduate course at the College of Medicine, Newcastle, on Bacteriology.

*Northumberland and Durham Medical Society.*

At the October meeting of this Society several specimens and cases of more or less interest were brought under the attention of the members. Amongst them were the following:—Dr. Robertson showed a man aged sixty-seven, who for twenty years had some difficulty in swallowing. During six weeks before operation very little food could be taken, and most of it was speedily returned. Obstruction was discovered by use of the sound fourteen inches from the lips. Gastrostomy was performed in July. The patient has been fed only by artificial opening since, for no food would go down the normal route. The man is at work daily, and since the operation has gained a stone in weight. The fistula causes no trouble by leakage. Dr. Robertson also exhibited a case of mastoid disease, showing recent methods of operating.—Mr. Black brought forward a case of excision of wrists. The patient, a girl of ten, had been treated by rest for some months, but this failed to arrest the disease. A straight incision (dorsal) was made in the line of the extensor indicis. All the carpal bones, except the trapezium and pisiform, were removed; also the bases of the second and third metacarpal bones and the centre of the end of the radius with the diseased synovial membrane. The result of the operation was entirely satisfactory.—Dr. Drummond showed a case of multiple cerebro-spinal sclerosis. Two points made the case specially interesting—(1) the diagnosis could be made with certainty; (2) the lesion began in the brain, which was rare. The patient, aged thirty-one, somewhat suddenly after an indefinite illness developed slight left hemiplegia. Within a fortnight diplopia followed; later, difficulty in swallowing and slowing of speech. There were now present almost constant movements of head, nystagmus, tremor of hands, rigid lower extremities, with increased knee jerks and ankle-clonus. Dr. Drummond also showed a girl, aged fourteen, suffering from chronic chorea for five years. She has taken arsenic for four years and now shows marked pigmentation of the skin, of a peculiar yellow tint best marked at the root of the neck, round the breasts and about either axilla.—Mr. Rutherford Morison showed a man, aged seventy-seven, the whole of whose lower lip he had excised for epithelioma, and a soldier who was admitted into the infirmary with a compound depressed fracture of the right parietal bone without symptoms. Two hours after the accident he was trephined. A lock of hair was firmly wedged in between the fragments and could not have been dislodged without elevating them. The disc of bone was cut into small pieces with bone forceps, washed well in 1.40 carbolic lotion, and the opening was packed with tus delvis. The wound healed by first intention without drainage. Some disappointment was felt now, for there was a well-marked depression over the trephine hole

evidently from subsequent absorption of part of the new bone, though no portion of the opening is soft. The case was intended to show the advantage of trephining in all compound depressed fractures, for without this it would have been impossible to secure asepsis.—Mr. Rutherford Morison also showed a patient whose vermiform appendix he had removed for recurring attacks of perityphlitis. Three weeks ago the operation was performed, and on examination the appendix was seen to be ulcerated and perforated at one minute spot, where it had fortunately contracted adhesions to the parietal peritoneum on the outer side of the cæcum. The patient recovered in the most uneventful fashion.—Dr. Hume showed a patient who had been operated on for suppurating hydatid of the liver.—Dr. Robertson showed a urethroscope and recommended its use in all forms of urethritis for diagnosis and treatment.—Mr. Rutherford Morison exhibited two ovarian tumours removed from women of the respective ages of seventy-seven and seventy-four.—Dr. Drummond exhibited the liver of a patient admitted to the infirmary moribund with jaundice and acute peritonitis. The post-mortem examination showed both to be due to the presence of an immense hydatid which had ruptured into the peritoneum in the liver.—Mr. Page exhibited a number of gallstones removed by cholecystotomy, and Dr. Murphy a variety of specimens in connexion with the pathology of abdominal organs.

Newcastle-on-Tyne, Nov. 2nd.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Edinburgh Improvement Scheme.*

THE Edinburgh Town Council, as local authority, have under consideration a provisional Act, to be known as the Edinburgh Improvement (Housing of the Working Classes Act) Scheme. This Act is specially intended to deal with "slum property." It includes provisions for dealing—(1) with unhealthy areas so as to make them efficient for sanitary purposes; (2) the widening of existing approaches to unhealthy areas or for opening out the same for purposes of ventilation and health; and (3) providing accommodation for persons of the working classes displaced in those areas.

### *Edinburgh University Court.*

At the meeting of this court last week the following gentlemen were recognised as teachers whose courses qualified for graduation:—Dr. J. S. McLaren, in Surgery; Dr. P. H. Maclaren, in conjunction with Dr. C. W. Macgillivray, in Clinical Surgery; Dr. James Hodsdon, in Surgery, in charge of teaching rooms; and Dr. R. F. C. Leith in Pathology.

### *Edinburgh Royal Medical Society.*

The following gentlemen have been elected presidents for the year of this Society:—A. N. S. Carmichael, M.B., C.M.; J. W. Crerar, M.B., C.M.; Line Boorn King, M.B., C.M.; and Harry Rainy, M.A., M.B., C.M.

### *Leith and Public Health Matters.*

There is at present in Leith not only an epidemic of measles and scarlet fever, but there has also been an outbreak of typhus fever. The result is that there has been a greater demand for hospital accommodation than the burgh possesses, and the authorities have had to erect temporary structures. The authorities have had under consideration a site for their infectious diseases hospital which seems to be acceptable. There are six acres of ground, and the price is said to be £600 per acre. A suspicious case of illness from a steamer from Hamburg has been admitted into the observation wards, but no definite opinion has been pronounced as to its nature. The local authorities are again engaging the attention of the Board of Supervision. It appears that the Sanitary Association of Scotland has written to the board complaining that the person appointed sanitary inspector to the burgh was not a member of their Association and that he had no practical knowledge of the work of such a post. The board has transmitted this letter to the local authority.

### *Health of Edinburgh.*

The mortality last week was 87, making the death-rate 17 per 1000. Diseases of the chest caused 20 deaths and zymotic diseases 30, of which 4 were due to diphtheria, 3 to scarlet fever and 21 to measles. The intimations for the week were: typhoid fever, 4; diphtheria, 4; scarlet fever, 75; and measles 380.

### *General Council of the University of Edinburgh.*

The statutory half-yearly meeting of this body was held last week, Sir William Muir being in the chair. There was only a small attendance. The business included the order by Her Majesty in Council continuing the powers of the Universities Commissioners until Jan. 1st, 1894, and the intimation that certain ordinances, including some dealing with the medical faculty, had been approved by Her Majesty in Council. The report by the Committee of Council on Ordinances, which was submitted, dealt in the first place with the remit from the April meeting to promote an address from the House of Commons for reconsideration of certain ordinances. It traced the steps which the committee had taken and the result of the deputation to London, and the causes which led to the motion for reconsideration being defeated in the Commons. The statement made by Sir Henry Roscoe in the course of the debate in the House, that it was the intention of the Commission to make such an arrangement that the professors would be entirely independent of the fees of their own classes, and that there would be a fee fund, with a minimum salary fixed for each professor, was regarded by the Committee as a change which might be far reaching in its effect. It was looked upon as the admission of a new principle which would remove one of the chief obstacles in the way of reforms which had already been urged by the Council. The other reports submitted to the meeting were of no medical interest beyond the fact that the medical curriculum is taken as the type on which other departments in the University ought to be modelled.

### *Health of Aberdeen.*

Last week 503 cases of zymotic diseases were reported to the medical officer of health, including 454 cases of measles, 36 of scarlet fever, 8 of erysipelas and 1 of typhoid fever. On the whole, there was an increase of 68 cases on the number for the previous week.

### *Aberdeen University: Assistant Professorships.*

The following appointments were announced at a meeting of the University Senatus last week:—Mr. George Dean, M.A., M.B., C.M., to be Assistant to the Professor of Pathology; Mr. Alexander MacGregor, M.D., to be Assistant to the Professor of Practice of Medicine; Mr. Robert Gordon MacKerron, M.A., M.B., C.M., to be assistant to the Professor of Midwifery; and Mr. J. Wemyss Grant, M.B., C.M., to be Second Demonstrator of Anatomy.

### *Aberdeen Medical Staff Corps.*

Last week the 7th (Aberdeen University) Company, Volunteer Medical Staff Corps, held a highly successful smoking concert, Surgeon-Captain MacGregor presiding. He reviewed the work of the year, and intimated that financially they had a good balance in their favour. The prizes for drill and best kept tents were then distributed.

### *Aberdeen: Death of Dr. John Urquhart.*

We regret to announce the death of Dr. Urquhart after a long illness of nearly three years' duration. Dr. Urquhart, who was sixty-six years old, after studying at Aberdeen and Edinburgh Universities, graduated M.D. Edin. and afterwards obtained the M.R.C.S. Eng. He practised for twenty-two years in Madras, where he was coroner and professor of medical jurisprudence, and where he acquired a large practice. Returning to Aberdeen in 1870 he soon became known as a leading practitioner, and for long has been affectionately regarded as one of the fathers of the profession. He took a keen interest in all benevolent and philanthropic work, and was many years a manager of the Royal Infirmary, of the Lunatic Asylum and of the Public Dispensary. In the affairs of the local medical societies he was deeply interested and held office on the management of several. His funeral was attended by practically the whole of the medical profession in Aberdeen and by most of the leading citizens.

### *Glasgow Obstetrical and Gynaecological Society.*

Officers for ensuing session:—Honorary President, Sir Spencer Wells, Bart.; President, Robert Pollok, M.B.; Senior Vice-President, G. A. Turner, M.D.; Junior Vice-President, Thomas Richmond, L.R.C.P. Edin.; Treasurer, Alex. Miller, L.R.C.P. Edin. &c.; Secretary, J. Nigel Stark, M.B.; Reporting Secretary, Robert Jardine, M.D.; Pathologist, A. Milroy, M.D. Council—Robert Kirk, M.D.; H. St. Clair Grey, M.D.; Malcolm Black, M.D.; E. H. L. Oliphant, M.D.; A. Richmond, M.B.; and D. N. Knox, M.D.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

*Increase of Lunacy in Ireland.*

FROM the last report of the Inspectors of Lunacy, it appears that the number of lunatics under care has increased from 249 per 100,000 of the population in 1880 to 355 per 100,000 in 1891. Such an increase is a matter of grave concern. The large number (3,415,400) of people who have emigrated during the past forty years—tending to remove the healthy and strong both in mind and body, thus leaving a large number of the weak and infirm as a burden on the public rates—must be considered as one of the chief factors of this large increase. Hence it may be assumed that the present number of the insane in Ireland properly belongs to a much larger population than that which now exists. But making full allowance for this cause, which tends to show an apparent increase of insanity, it must be concluded that the large increase of lunacy has been absolute as well as relative. The rapid increase of insanity with a diminished population, the inspectors remark, ought to engage the attention of all who take an interest in the social and material progress of Ireland, in order to ascertain how far such increase can be stayed by any means within the power of the State.

*Grievances of Dispensary Medical Officers.*

A meeting of the Irish Poor-law Medical Officers' Parliamentary Committee was held last week, when the following resolution was adopted unanimously: "The members of the Irish Poor-law Medical Officers' Parliamentary Committee express their sincere regret that the Right Hon. John Morley, Chief Secretary for Ireland, declined to receive the deputation from the conjoint associations which was appointed to wait on him with reference to the questions of superannuation and the other admitted grievances of the dispensary medical officers, and, whilst deprecating any intention to inconvenience the Government in its work of legislation in the coming session, yet hope that the Government will give every facility to have the Bills submitted to the judgment of the House of Commons when introduced by private members."

*Royal University of Ireland.*

On the 29th ult. degrees were conferred by the President of the Queen's College, Galway, in the absence of the Chancellor and Vice-Chancellor. Among those present was his Excellency Lord Houghton. The candidates who entered for the various examinations during the year numbered 2857, showing a decrease of 27 as compared with last year, while there were 201 degrees conferred. A conversazione of the graduates, undergraduates and guests was held the same evening in the University buildings. A concert, military band, experiments in biological science and lantern slides illustrating the Arran Islands added to the attractions of the evening.

*Health of Dublin: September Quarter.*

The births registered amounted to 2441 and the deaths to 2010, or 23 per 1000, being 0.5 below the average for the September quarter of the past ten years. Zymotic diseases caused 323 deaths, or 97 over the number for the corresponding quarter of last year. Deaths from measles fell to 59, while scarlet fever only caused 5 deaths, typhus fever 1, ill-defined fever 2, and typhoid fever 21.

*Schools of Surgery: Royal College of Surgeons.*

On Tuesday last the distribution of medals and prizes awarded during the past session took place. Mr. Hamilton, President of the College, said that the Council had done everything that careful inquiry and expenditure of time and money could do to make the schools of surgery perfect and a credit to the College, but without the coöperation of the students their efforts would have been futile. An attempt had been made to transfer from the professors in Dublin the teaching of medicine and surgery. He would leave the professors to stand on their own record, and he thought when they came to be weighed in the balance they would be found equal to those who would fain supplant them. The important question for everyone concerned, medical men and the public alike, was whether the movement he had referred to would be for the benefit of the hospitals themselves. He thought it would not. A fifth year had lately been added to medical study, and with all due deference to the General Medical Council he believed that it was a great mistake. He wished the Council had rather turned their attention to a

really weak link in the system—namely, preliminary education. He felt satisfied that the boy who had been thoroughly trained would grasp more of his medical studies in four years than he would under the present system in six years. But the boy must be trained, not crammed, and what was wanted was a good boarding school, where boys, on moderate terms, could have a training which would fit them for entering schools of surgery and medicine.

Mr. J. Kellock Barton, ex-President and Member of Council of the College of Surgeons, has resigned his seat as Councillor. Mr. F. T. Heuston will be a candidate, and the names of Mr. Swan and Mr. Humphrey Broomfield are also mentioned.

Nov. 1st.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Medical Treatment of Rectal Cancer.*

THE question of medical treatment of cancer of the rectum, in contradistinction to surgical procedure, is an interesting one, seeing that the latter is of so little promise in many cases and that a very short immunity only from recurrence is obtained after running the gauntlet of a severe surgical operation. For such cases, where the disease is advanced and the progress slow, M. Dujardin-Beaumetz has devised a plan of treatment of which he reports favourably and which he credits with being able to prolong the patient's life longer than could be hoped for after an operation, even when successful. With this end he has recourse to intestinal washings with antiseptic solutions, so as to arrest, or at least diminish, the progress of the malady by removing the pus and secretions frequently. A solution of naphthol—ten to twenty centigrammes per cent.—is what he advises. In addition to this he disinfects the intestinal canal by exhibiting salol or benzo-naphthol with bicarbonate of soda, in wafers by the mouth. Laxatives must also be given to prevent any accumulation in the colon, and M. Beaumetz is of opinion that a diet consisting largely of vegetables is also advisable. He has at present under observation three patients suffering from rectal cancer who for the last three years have been subjected to this method of treatment and who have even gained in flesh. He is satisfied that the method is superior to extirpation.

*Monopolies versus Therapeutics.*

France is the country *par excellence* of monopolies and commercial or industrial protection. Every visitor to *la ville Lumière* knows how these overshadow the common necessities and ordinary conveniences of life—such, for example, as in the matters of water, gas, lucifer matches, tobacco and cigars, omnibuses &c.—and the citizen of this enlightened republic of vaunted liberty, equality and fraternity is reduced to Hobson's choice. He must have what is provided for him by the powers that be or go without; the alternative provided by healthy competition is out of the question. It will scarcely be credited, however, that this system of monopoly and exclusiveness extends to the domain of therapeutic agents; and yet it is so. For instance, the market is flooded with an endless variety of French mineral waters—a few good, others bad, but the great majority indifferent. Foreign competition is discouraged by interested persons and influential companies, and vexatious obstacles and delays are thrown in the way of the introduction of any foreign mineral water—where, indeed, this latter is not altogether excluded. I have had an instance of this recently in my own practice. I ordered a patient suffering from gout a German mineral water which is being largely prescribed in such cases by my teachers, the physicians of the British school, but was unable to procure the water, as its sale was unauthorised in France! Where, however, foreign water is long and universally recognised to be unequalled by any French production of its kind, it is admitted, on sufferance, with attached conditions. Of course, successful springs have their French competitors and allies, the chemical composition of which may bring them into apparently close therapeutic relationship. But, as has been well pointed out by Sir Henry Thompson, a like chemical composition by no means implies a like therapeutic effect.

*Insanitary Kitchens in Paris.*

Foreigners who enjoy the occasional luxury of a dinner at a fashionable Paris restaurant little dream of the unhealthy, not

to say disgusting, surroundings of the myrmidons whose duty it is to prepare the appetising viands sent upstairs. A peep at the kitchen in too many celebrated establishments would assuredly have the effect of dispelling the appetite of even a burly Yorkshire farmer. That I do not exaggerate is abundantly proved by the report just made to the Conseil d'Hygiène de la Seine by M. Deschamps. This report is based on the investigations of Drs. Calendreau and Regcard, medical officers to the Société des Cuisiniers de Paris. Dr. Regcard says of these kitchens that they are, in fact, the foulest rooms in the house—airless, because the ventilators are kept closed in order to avoid odours in the dining-rooms and in neighbouring houses; often also deprived of any other than gas light. The water-closets are generally in direct communication with the kitchen, and, in many instances, access to them being forbidden during the busy hours of the day, the cooks are compelled to utilise preserved fruit and vegetable boxes as urinals. All the above details are sufficiently disgusting to the customer, but the report would be incomplete were no reference made to the disastrous effects of these insalubrious conditions on the health of the men who pass their lives in these dirty holes. Dr. Calendreau tells us that, in addition to infirmities such as varicose veins, varicocele and hernia, which are peculiar to the calling, cooks suffer from the following maladies: (1) Rheumatic pains from damp, absence of fresh air and light; (2) sore-throat and bronchitis, due to exposure to draughts and excessive heat, with consequent indulgence in iced beverages; (3) dyspepsia and alcoholism; and (4) pulmonary phthisis. The foregoing list explains the high mortality prevailing amongst this numerous class. The remedy proposed for this deplorable state of things is as follows: No restaurant kitchen to have dimensions less than, length, 3 metres; breadth, 2 metres 50 centimetres; height, 2 metres 80 centimetres; every kitchen to be independent for air and light of small courtyards; the kitchen to be separate from the scullery; the floor to be waterproof; the larder to be isolated; urinals and closets to be quite apart from the kitchens; the suppression of bedrooms in proximity with the kitchens. The Municipal Council has had the above reforms under consideration, and we shall, I trust, soon see them put into execution.

Paris, Nov. 2nd.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *Cholera in Austria-Hungary.*

At the time when the first case of Asiatic cholera was admitted to the Hospital for Epidemic Diseases, two other suspected cases were brought there in which the presence of the comma bacillus could be proved. One of these died on Oct. 28th, and after a post-mortem examination the case was pronounced to be one of Asiatic cholera. The patient was a boatman who had arrived at Vienna, on the day of his admission to the hospital, from Hungary, on board a ship belonging to the Danube Regulation Company. The other case in which the comma bacillus was also found was that of a labourer who had worked on the Danube embankment, and who had been infected, as is supposed here, by carrying infected linen and rags which were unloaded here from Hungarian boats. He is now recovering. No other cases of real cholera have occurred in Vienna since these three cases have come under observation, though eight to ten suspected cases of intestinal diseases were sent daily to hospital by anxious physicians. This cholera-phobia among the physicians—which proved sometimes very serious to the patients from a social point of view, as their lodgings and shops were put under quarantine—is due to the fact that the younger generation of physicians have had no opportunity of seeing a case of cholera during their medical practice, and older physicians who have been in active practice during a cholera epidemic ought to have been appointed by Government to examine these suspected cases. The official return issued by the Upper Medical Council states that up to Oct. 28th 136 cases of cholera have occurred in Austria since the outbreak of the disease—130 of them in Galicia and Cracow and its environs. No official report on the statistics of the number of deaths from cholera in Hungary has appeared as yet, but the daily number of cases at Budapest and in the provinces may be estimated as between 30 and 40.

Vienna, Oct. 31st.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *Cholera and Quarantine.*

THE recent public excitement over the appearance of cholera at quarantine has entirely subsided. There is now neither cholera at quarantine nor in the city. The experiences of many prominent citizens at quarantine are destined to have an important influence upon future legislation. Hitherto it has been very difficult to impress public men with the deficiencies of our quarantine system and obtain needed reforms. But now senators, clergymen, physicians, lawyers and newspaper men have been caught in our quarantine trap, and compelled to endure not only all the inconveniences, but all the hardships, and even perils, which our quarantine imposes upon the luckless traveller. Whatever may be the shortcomings of the health officer—and they are doubtless many,—there are glaring defects in our quarantine which it is to be hoped will now be remedied. Perhaps the most important defect is inadequate space for the purposes of a modern quarantine. The extreme accommodations of the establishment are for 750 persons, and yet there were upwards of 4000 people at one time demanding immediate removal from infected ships and isolation in proper quarters for their care. It was impossible to meet this emergency at once and hence the hardship of detention on board ship. The condition was the more alarming to cabin passengers inasmuch as they were ignorant of the fact that cholera prevailed among the steerage passengers until the ships were anchored in the bay, within sight of the city. Then they learned that they were on cholera-infected ships, and that they must remain from five to twenty days after the last case had appeared, as there was no possible method of accommodating them within the quarantine grounds. What added to the excitement was the constant occurrence of new cases among the steerage passengers and the danger that the infection would reach the cabin or first-class passengers, so impossible was it to cleanse and disinfect in the presence of crowds of passengers. Hundreds of men and women who had braved the perils of the sea found themselves within sight of home, helpless in the presence of an increasing and threatening pestilence. Public excitement became intense, meetings were held and committees appointed to rescue them. One citizen purchased a steamboat for \$30,000 and sent it to their relief. An appeal was made to the General Government to create a camp on Sandy Hook, to which the healthy passengers could be removed. The Government responded promptly, but it required time to erect and provision a camp. The Governor also came to the rescue and purchased Fire Island, a summer resort, and turned it over to the health officer. The Chamber of Commerce raised a relief fund of \$250,000. But all these measures were destined to fail to give prompt relief. The steamboat proved to be almost uninhabitable, as it was out of repair and unseaworthy. The passengers who were removed to it found their discomforts increased, and though they had escaped the risk of contracting cholera, they now incurred the dangers of fire and water. Those passengers who were conveyed to Fire Island were in still greater perils. They had a voyage of forty miles on the open sea in a small river craft unprovided with such common furniture as chairs, beds &c. During the passage, which was made at night, a storm arose which threatened the frail vessel with its 250 passengers. When it reached its destination the pilot could not find the channel to the bay, and the vessel had to return to the New York harbour in the teeth of the storm. Travellers report that they never experienced such hardships by sea or land. Old people and children suffered intensely, but happily no deaths occurred. On the following morning the vessel was ordered to return and the wretched passengers, sick and suffering and without food, had to endure the third perilous voyage over the rough sea. The close of this last trip witnessed a scene which might well have occurred on the coast of Africa. The vessel passed into Great South Bay with its human freight in the last stages of suffering for the want of food and from the incessant exposure to the hardships of the three voyages. As they approached the island they were met by men in boats, who not only refused to allow them to land, but even forbade them being supplied with food. Strong men earnestly appealed to these inhuman wretches to provide food for sick children and old people, but they not only refused, but one man waved a loaf of bread

upon a pole to tantalise the sufferers. Relief came only when, under the orders of the Governor, the military took possession of the island. The camp at Sandy Hook was finally completed and the steerage passengers were removed to it, thus relieving the steamships of their inhabitants. The difficulties of quarantine were complicated by an outbreak of measles among the children of the immigrants, which assumed large proportions. The cases of cholera, however, diminished rapidly and soon ceased to recur. At the close of the month the harbour was free from cholera.

October, 1892.

## THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### MEETING OF FELLOWS AND MEMBERS.

THE annual meeting of the Fellows and Members of the Royal College of Surgeons of England was held on Thursday in the theatre of the College. There was a fair attendance.

Mr. THOMAS BRYANT, President of the College, occupied the chair. In the course of his opening remarks he said that this was the ninth consecutive annual meeting of the Fellows and Members of the College, and it would be gratifying if, when the meeting was over, they could all come to the conclusion that it had been of advantage to the Fellows and Members and to the credit of their great institution. The report which the Council had presented was a complete epitome of the work of the past collegiate year. It contained everything that could be of any interest to the Fellows and Members. The curriculum of study had been carefully and fully considered and the Fellows and Members of the College might look upon the scheme as complete and well considered. There was little to be said about the new university for London, for the question was now under the consideration of a Commission. At present the College had nothing to do with it; they had given evidence before the Commission and they were considering the evidence as it went on. He need hardly say that probably when the proper time came, they might sketch out some sort of scheme, which probably would be laid before the Fellows and Members. As to the further advantages conferred on Fellows, he would say that it had been gratifying to the Council to feel that their hands were comparatively free in the matter, and he hoped they would be able to hear on this occasion that the Fellows were fairly satisfied with what the Council had done. There was an amusing mistake in the report. It was stated that during the past year the Council had had under their consideration two cases of misconduct by "Members of the Council" in which they had inflicted the penalty of removal. There was something rather humorous in this, but of course it meant "the Members of the College." He thought the meeting would agree with the Council in seeking to purge the College of any men who had transgressed the law of the land. Whenever their attention was called to any act of any Member of this College which they considered prejudicial to the interests or derogatory to the honour of the College, or disgraceful to the profession, they wrote and asked whether such and such an advertisement or statement was true or not, and when necessary they assured the man that such conduct was against the declaration he made when he became a Member of the College. They had good reason to believe that in this way they had obtained most excellent results. As to the museum, he might say that the extraordinary expenditure in connexion with it had come to an end and they had paid the last cheque, and he thought they had got their money's worth. As to the library, he did not think they had anything to say in the way of fault-finding. It was certainly the most satisfactory library for working in anywhere in the world. The finances of the College were in a satisfactory condition and the Council contemplated the future without anxiety.

The Assistant Secretary intimated that notice of the following resolution had been given by Mr. Lawson Tait and Mr. Nelson Hardy—viz., "That this meeting of the College of Surgeons of England is of opinion that the report now presented is ineffective and incomplete, and this meeting is further of opinion that the ancient attitude of hostility on the part of the Council to the true interests of the body corporate of the College ought to terminate, and that the repeated resolutions passed at former meetings of this College should be carried into effect."

The President suggested to Mr. Lawson Tait that the

resolution should be divided in two. He might have been pleased perhaps if he had felt it fully expedient to say that this resolution should not be submitted to the meeting. He need hardly say that it had a sting of an offensive character in it which was not quite consistent with the good feeling with which he hoped they had all met. He would be glad if the proposer and seconder and their supporters saw their way to withdraw the resolution. (Cries of "No, no.") At any rate, the meeting had heard the resolution read, and he thought it would be wise to put to the meeting the question whether the resolution should be put. He would prefer the meeting to say that it should not be put.

Mr. Lawson Tait: You cannot do that until your hear the matter argued.

The President: The first part may be put. We do not recognise an "ancient attitude of hostility" on the part of the Council.

Mr. Lawson Tait: But we do, which is the whole thing.

The President, continuing, said the resolution quickly suggested that the Council of the College was not acting in the true interests of the body corporate. If that was an expression of opinion the Council would take it for what it was worth and let it go on. It was an extremely offensive resolution, and he was very sorry it should be before the meeting. He ruled that it be divided.

Mr. Lawson Tait said he knew of no meeting conducted in such an extraordinary fashion as this. He had never heard a chairman argue a resolution before the opener had spoken, and he had never heard of any business body in this world begin a meeting as this meeting had been begun.

The President invited Mr. Lawson Tait to address himself to the resolution.

Mr. Lawson Tait said he would do that in good time. For the present he would give reasons why the resolution should be considered as a whole and not divided. The resolution had been accepted by the secretary in the course of correspondence that had taken place on the subject. If it must be altered he considered that there had been a breach of bargain. He would submit, however, to the division of the resolution. He denied that there was anything offensive in it. Less offensive words than "ineffective and incomplete" could not be used. The report was incomplete for this among other reasons—that it gave no sufficient information with regard to the question of a new university for London. As to the curriculum of study, it did nothing for the student except to give him an additional year of study. While good enough so far as it went, it was manifestly the work of academic men who soared in the clouds above the wants of the medical profession of the day. Had there been on the Council Members of the College engaged in general practice the scheme of study would have been very different indeed. He begged to move: "That this meeting of the College of Surgeons of England is of opinion that the report now presented is ineffective and incomplete."

Mr. Nelson Hardy, seconding the resolution, said the report should not merely be presented, but should be open to correction and, if necessary, to rejection. From the statement of the President himself it would appear that at least one matter in the report required correction.

Mr. George Brown supported the resolution mainly on the ground that the report lacked the information about the university scheme to which he thought the Fellows and Members entitled.

Mr. Craven (Hull) said he did not take this gloomy view of the situation. He knew of no college better managed than this. No one could bring a word of complaint against the management. To this opinion he adhered, in spite of what others might say to the contrary.

Dr. Danford Thomas spoke in support of the resolution.

Mr. Square (Plymouth) moved as an amendment, "That this meeting respectfully begs that the report be referred back to the Council for reconsideration, to be brought up again at an adjourned meeting."

The President: I cannot put that. It is not in the power of this meeting.

Surgeon-Major Ince said he found himself in the midst of a body of fighting men, although he himself was not a fighting man. He begged to move, "That this meeting regards this report as satisfactory, and acknowledges the liberality of the Council."

This motion was ruled out of order.

Mr. Holmes said he did not intend voting on the resolution. He recognised in the report a very great deal which he thought would be for the benefit of the Fellows.

A show of hands was then taken, when 10 persons voted

for the resolution and 16 or 17 against it. The resolution was accordingly lost.

Mr. Lawson Tait then moved the second part of the resolution, namely: "And this meeting is further of opinion that the ancient attitude of hostility on the part of the Council to the true interests of the body corporate of the College ought to terminate, and that the repeated resolutions passed at former meetings of this College should be carried into effect."

Dr. Alderson seconded the resolution.

Mr. Joseph Smith said he wished to clear up a misapprehension about the costs in the recent litigation. The College had asked for its costs and it would get its costs. He and his friends expected nothing gracious from the College in this matter.

Surgeon-Major Ince urged Mr. Lawson Tait to withdraw the resolution, saying that he ought to be gentle and forbearing to the Council. Let them conclude the meeting in a peaceful and friendly manner.

The President before putting the resolution to the meeting said that he supposed it would be useless for him to assure Mr. Lawson Tait and his friends that if there ever was any "ancient hostility" on the part of the Council, there was none now. The Council were doing their very best for the body corporate.

The resolution was carried by twenty-five votes to ten.

Mr. Homes, on behalf of the Association of Fellows, moved: "That this meeting of Fellows and Members desires to thank the Council of the College for acceding to their wishes in the matters (a) of separate meetings of Fellows and Members, and (b) of the provision of a Common Room in the College."

Dr. Bradford Thomas seconded the motion and it was carried with only one dissident, namely, Mr. Lawson Tait.

Mr. F. Gant moved, also on behalf of the Association of Fellows: "That this meeting of Fellows and Members wishes again to impress upon the Council that it is absolutely essential for the welfare of the College that the Fellows and Members should be consulted before any change is made in the constitution and external relations of the College and before the College is committed to any extraordinary expenditure on buildings or otherwise."

The President explained that the Council had had this matter under their consideration on many occasions, and there was a kind of undertaking between them that in any important change in the constitution of the College they should consult the Fellows and Members.

Mr. Joseph Smith seconded the motion.

Mr. Lawson Tait asked for information about the undertaking of which the President spoke.

The President said that as long ago as Nov. 17th, 1885, the Council, after considering certain resolutions passed at a meeting of Fellows and Members, agreed, "That with the larger questions which more rarely arise, such as those which concern the constitution of the College, the course will be different. Upon those questions the Council will always be glad to have an opportunity, so far as practicable, of consulting the Fellows and Members."

Mr. Lawson Tait said he had seen no disposition on the part of the Council to take advantage of this resolution.

The President reminded him that there had been meetings in connexion with the expenditure upon the museums and the university question.

The resolution was carried by 22 votes to 2.

A vote of thanks having been accorded the President the meeting terminated.

**A FREE GIFT.**—Abington Abbey together with twenty acres of land has been offered to the Northampton Town Council for use as a people's park by Lord and Lady Wantage.

**A NEW MEDICAL SOCIETY.**—A new society has been started in Oxford for the discussion of subjects connected with medicine and surgery. The first meeting is to be held on Nov. 11th, when Sir James Paget will deliver an inaugural address. Sir Henry Acland has been chosen as the first President, the vice-Presidents being Professor Burdon-Sanderson and Mr. Alfred Winkfield, Dr. Collier acting as secretary and treasurer. The ordinary meetings of the Society will be held on the second Friday in each month.

## Medical News.

**ROYAL COLLEGES OF PHYSICIANS OF LONDON.**—The following gentlemen having conformed to the by-laws and regulations and passed the required examinations were at the quarterly meeting of the College admitted Licentiate:—

Alston, H., University College.  
Anderson, C. M., Edin. and Guy's.  
Atchley, E. G. C. F., Bristol.  
Atkinson, H. N. C., St. Barthol.  
Auty, C. H., St. Bartholomew's.  
Badham, R. C., Sydney & London.  
Bailey, Thos. Wm., Westminster.  
\*Baldwin, Henry Clifford, Leeds.  
Barnard, Harold Leslie, London.  
Beckite, James Clay, Glasgow.  
Bensusan A. D., St. Thomas's.  
Bernard, Claude, Bristol.  
Brabant, R. H. W. H., Guy's.  
Bradshaw-Isherwood, Percy A., St. Bartholomew's.  
Brasher, Chas. Wm. Jas., Bristol.  
Brisley, Chas. W. St. Thomas's.  
Bryant, Hugh Arnold, Guy's.  
Buck, Arthur H., St. Barthol.  
\*Bury, Reginald F., St. George's.  
Campbell, J. A. L., Westminster.  
Carter, Hugh Ronald, St. Mary's.  
Cartwright, Ernest H., Oxford and Guy's.  
Clarke, Hugh C. W., Manchester.  
Colmer Ptolemy A., London.  
Cook, Fredk. Ernest, Liverpool.  
Cooper, Dossabhoy N., Madras and St. Bartholomew's.  
Covey, W. J., University College.  
Cresswell, Frank P. S., Guy's.  
Crofts, George Harry, Liverpool.  
Crosland, Geo. Wm. K., Leeds.  
Dixon, Thomas, Birmingham and St. Mary's.  
Duka, Albert T., Camb. Univ. and St. George's.  
Dutton, Arthur S., St. Thomas's.  
Edwards G. M., Camb. & Middx.  
Killick, Harry Scott, St. George's.  
Evans, James Arnold, Liverpool.  
Fawcett, Rupert, St. Thomas's.  
Floury, Charles Marlay, Guy's.  
Floyd, Stephen George, Guy's.  
Foulkes, Thos. H. St. Barthol.  
Fraser Luckie, H. O'Naghton, St. Bartholomew's.  
Furnivall, P., St. Bartholomew's.  
Gains, John Edwin, Leeds.  
Gardner, Harold, Charing-cross.  
Gilbert, Charles William, London.  
Gillbard, Richard, Guy's.  
Goldsmith, Geo. H., St. George's.  
Goodwin, Edwd. K., King's Coll.  
\*Gover, Lawford D., St. Thomas's.  
Grace, Gerald, Bristol.  
Green, S. F. St. David's, St. Barthol.  
Gregar, Charles Granville, Guy's.  
Harding, H. W. L., St. Barthol.  
Hawkins, Edwd. J., St. Barthol.  
Hayes, Geo. C., King's Coll. and Melbourne.  
Henry, Edwin, St. Bartholomew's.  
Hepton, J. C., Manchester & Glasg.  
Heywood, Thomas, St. Mary's.  
Hicks, Thos. Wm., St. Thomas's.  
Hine, Alfred E., Charing-cross.  
Holtings, W. W., University Coll.  
Hollings, Edwin Thomas, Leeds.  
Hooper, G. H. J., Charing-cross.  
Huntley, Edgar, Guy's.  
Jago, Ashley Filsted, Guy's.  
Jeaffreson, G. C., University Coll.  
Johnson, Lawrence A., Leeds.  
Jones, Geo. David E., Middlesex.  
Jones, Geo. Reginald, Liverpool.  
Keels, David, University College.  
Kendall, N. F., St. Barthol.  
Kendrick, Horace H., London.  
Kingsford, B. H., St. Thomas's.  
Knightley, W. R., St. Barthol.  
\*Kobla, D. H., Bombay & Middx.  
Leumann, B. H. F., St. Barthol.  
Levy, Alfred G., University Coll.  
Lewis, Fredk. H., St. Barthol.  
Lister, Thomas David, Guy's.  
Lucas, William F., Middlesex.  
MacPhail, John A., McGill Coll., Montreal, and London.  
Mason, F. H., Durham & Birm.  
Maw, H. T., St. Bartholomew's.  
Meade-King, R. L., St. Barthol.  
Merewether, A. E., Durh. & Lond.  
Mitton, A. H., King's College.  
Nankivell, B. W., Middlesex.  
Newton, Isaac, Charing-cross.  
\*Newton, R. F. H., St. George's.  
\*O'Ferrall, E. F., Charing-cross.  
Palmer, C. S., St. Bartholomew's.  
Paterson, Hugh Gordon, Leeds.  
Paterson, H. John, St. Barthol.  
Parry, T. W., Camb. & St. George's.  
Perran, E. A., St. Barthol.  
Planck, Charles, St. Thomas's.  
Quennell, Arthur, St. Barthol.  
Kedpath, W. St. Thomas's.  
Roberts, H. Wm., St. George's.  
Roberts, Sydney John, Guy's.  
Robinson, Frederick A., Guy's.  
Robinson, Geo. Burton, London.  
Robinson, Waring, Middlesex.  
Romer, R. Leslie, St. George's.  
Roche, Ernest Morley, Guy's.  
Rubra, Henry H., Birmingham.  
Scott, Francis Gilbert, London.  
Shillito, Alfred A., St. Barthol.  
Smith, Reginald, Manchester.  
Smith, T. R. H., St. Barthol.  
Stanton, Jas. Wm. W., London.  
Stokes, Whitley, St. Thomas's.  
Thomas, J. Morgan M., Bristol.  
Thorne, Atwood, St. Mary's.  
Tootal, John H., St. Barthol.  
\*Turnor, Philip W., St. George's.  
Vince, Thomas S., Birmingham.  
\*Walker, E. G. A., St. Barthol.  
Walker, Hyde Edwards, London.  
Webb, Chelmondeley, St. George's.  
White, Herbert G., St. George's.  
White, William, Middlesex.  
Wilkes, Geo. A., Birmingham.  
Wilkinson, Sidney, Liverpool.  
Williams, E. M., St. Barthol.  
Williams, R. H., University Coll.  
Wilson, Norman O., St. Barthol.  
Woodcock, A. H., St. Thomas's.  
\*Worrall, Chas. Lloyd, Middlesex.

\* Candidates who have not presented themselves under the Regulations of the Examining Board.

**CAMBRIDGE UNIVERSITY.**—At a congregation held on the 27th ult. the following medical degrees were conferred:—

*Bachelors of Medicine and Bachelors of Surgery*—Augustus Moore Daniel, Trinity; Edward Balnes and Sidney Edward Barrett, Gonville and Caius.

**LITERARY INTELLIGENCE.**—A new weekly Russian medical journal has just appeared under the title of *Iuzhno-Russkaya Meditsinskaya Gazeta*, or South Russian Medical Gazette. It is published in Odessa and serves as the organ of the Odessa Medical Society. The first number contains an article by Prof. Mechnikoff on Present Tendencies in the Treatment of Infectious Diseases and one by Dr. Starkoff on International Precautions in Turkey and Egypt against the Entry of Cholera into Europe from India, together with abstracts from other journals, the Society's proceedings, and general medical news.

**MEDICAL MAGISTRATES.**—Mr. Henry Aldred, L.R.C.P. Irel., M.R.C.S., of Manchester, Dr. George Herbert Pollard of Southport, and Dr. Edward Sword Morley of Blackburn have been placed on the Commission of the Peace for the city of Manchester and the boroughs of Southport and Blackburn respectively.

**FOOTBALL CASUALTIES.**—A youth while playing a game at Dalby on the 22nd ult. fractured his femur. The following casualties occurred last week:—During a match at Badsley Moore-lane a member of the Rotherham Thursday team "broke his ankle." In a match between the Small Heath and Darwin teams a member of the former team sustained a fracture of the leg and was admitted to the Queen's Hospital. Whilst playing a game with Repton School one of the full backs of the Derby County Team fractured his clavicle. At Cambridge, in a match under Association rules, a player sustained a compound fracture of his left leg.

**ROYAL ACADEMY OF MEDICINE IN IRELAND.**—The following office-bearers have been elected for the ensuing year:—President: George H. Kidd. General secretary: William Thomson. Secretary for foreign correspondence: J. W. Moore. Medical Section—President: Walter G. Smith. Council: Wallace Beatty, J. Hawtrey Benson, M. A. Boyd, E. M'Dowel Cosgrave, J. Magee Finny, Richard A. Hayes, J. W. Moore, A. N. Montgomery, G. P. L. Nugent and H. C. Tweedy. Surgical Section—President: Edward Hamilton. Council: Kendal Franks, F. T. Heuston, John Lentaigne, Austin Meldon, Thomas Myles, Edward Stamer O'Grady, Sir W. Stokes, W. Thornley Stoker, R. L. Swan and W. I. Wheeler. Section of Obstetrics—President: A. J. Horne. Council: L. Atthill, Robert W. Flynn, R. H. Fleming, F. W. Kidd, J. L. Lane, S. R. Mason, T. More Madden, R. D. Purefoy, A. J. Smith and W. J. Smyly. Section of Pathology—President: C. J. Nixon. Council: A. W. W. Baker, A. H. Benson, H. Bewley, J. Magee Finny, Edmond J. MacWeeney, J. O'Carroll, R. G. Patteson, J. M. Purser, J. A. Scott and J. B. Story. Section of Anatomy and Physiology—President: H. J. Broomfield. Council: A. Birmingham, H. St. J. Brooks, D. J. Cunningham, E. L. Ledwich, H. C. Earl and Alec Fraser. Section of State Medicine—President: E. M'Dowel Cosgrave. Council: Thomas Donnelly, Edgar Flinn, Ninian Falkiner, T. W. Grimshaw, J. W. Moore and J. M. Redmond.

**REQUESTS AND DONATIONS TO HOSPITALS.**—The late Mr. William Baker of South Retford bequeathed £100 to the Retford Dispensary and Cottage Hospital.—Mr. Josiah G. Strachan, late of Farmhill Park, near Stroud, bequeathed £1000 to St. Mark's Hospital for Fistula, and £500 each to the British Hospital for Diseases of the Skin, the Cancer Hospital, Brompton, and the Central London Throat Hospital.—The workmen of Sir W. G. Armstrong, Mitchell and Co., at Elswick, have contributed £270 9s. 10d. to the local medical charities for the quarter ending September last, of which £192 14s. 10d. has been apportioned to the Royal Infirmary, Newcastle.—The Goldsmiths' Livery Company has made a grant of £250 to the Royal Sea-bathing Infirmary for Scrofula, Margate.—The workmen of Messrs. R. and W. Hawthorn, Leslie and Co., Newcastle, have contributed £60 5s. for the quarter ending September last to the Newcastle medical charities.—Mrs. H. Wood, late of Bingley, bequeathed £200 to the Bingley Cottage Hospital.—The late General Doria bequeathed £1000 to the Chelsea Hospital for Women.—The Mercers' Livery Company has voted 100 guineas to the Cancer Hospital (Free), Fulham-road, S.W.—The late Mr. Lawson Robinson of St. George's-street bequeathed £100 to the London Hospital and £50 each to the Tower Hamlets Dispensary, the East London Hospital for Children, the City of London Hospital for Diseases of the Chest, and the Royal Hospital for Incurables.—The honorary secretary to the Leeds Musical Festival Committee has sent a cheque for £1300 to the Leeds Infirmary.—The sum of £92 2s. 2d. has been handed to the treasurer of the Belgrave Hospital for Sick Children, being the proceeds of the united demonstration of the temperance, trade and other societies held in July last in aid of that institution.—The late Mr. Thomas Nelson, publisher, Edinburgh and London, bequeathed £5000 to the Edinburgh Royal Infirmary.—The late Mr. John McCormick bequeathed £500 to the Cripples' Home, Bray, £500 to the City of Dublin Hospital and £500 to the Adelaide Hospital, Dublin.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADDENBROOKE, E. H., M.R.C.S., has been appointed Medical Officer for the Wolverley Sanitary District of the Kidderminster Union.

BAINES, E., M.B., B.C. Cantab., has been appointed Second House Physician to the General Infirmary, Leeds.

BRITTON, THOMAS, M.D. St. And., M.R.C.S., D.P.H. Camb., has been reappointed Medical Officer of Health to the Shelf Local Board.

CAMPBELL, JAMES, M.B. Glasg., L.R.C.S. Edin., has been appointed a Public Vaccinator, Clunes, Victoria, Australia.

CLARK, F. W., L.R.C.P. Lond., M.R.C.S., has been appointed, *pro tem.*, Assistant Medical Officer of Health for the Tyne Ports.

CRAYEN, ROB. M., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Westmoreland Combined Sanitary Districts.

CROSLAND, G. W. K., M.R.C.S., L.R.C.P., has been appointed Fourth House Surgeon to the General Infirmary, Leeds.

DUKE, A. F., L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Cheltenham Union, vice Walters, deceased.

EKINS, A. E., has been appointed County Analyst for Hertfordshire.

ENGLISH, T. H., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Junior House Surgeon to the Poplar Hospital for Accidents, East India-road, E.

FIRTH, E., L.S.A., has been appointed Resident Obstetric Officer to the General Infirmary, Leeds.

FOSBROOKE, G. H., M.R.C.S., D.P.H. Camb., has been reappointed Medical Officer of Health for the Worcestershire Division of the Alcester Rural Sanitary Authority.

FRASER, D. A., M.D. Brux., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Totnes.

GORNALL, J. G., M.A., M.B. Cantab., M.R.C.S., L.R.C.P., has been appointed Assistant Medical Officer of Health for the Borough of Warrington and Medical Superintendent of the Hope Hospital for Small-pox.

HAWORTH, JOHN, has been appointed Analyst for the Borough of Tiverton.

HILLIER, T. ERNEST, M.A., M.B. Cantab., M.R.C.S., L.S.A., has been appointed Medical Superintendent to the Infirmary and Medical Officer to the Workhouse of the Parish of Paddington, vice T. Savill, M.D. Lond., resigned.

HODSON, FREDK., M.R.C.S., has been appointed Medical Officer of Health for Hornsea-with-Hornsea, Burton Urban Sanitary District, of the Skirlaugh Union, vice Thompson.

HOGG, G. H., M.B., C.M. Edin., has been appointed Junior House Surgeon to the Clayton Hospital, Wakefield, vice Wait, resigned.

HUGHES, W. L., M.R.C.S., has been reappointed Medical Officer of Health to the Carmarthen Town Council.

JACKSON, JOS. J., L.R.C.P., L.M. Edin., L.R.C.S. Irel., has been appointed Medical Officer of Health for the Rural Sanitary District of the Wakefield Union, vice Walker, resigned.

Saturday, November 12.  
**UNIVERSITY COLLEGE HOSPITAL.**—Operations, 2 P.M.; and Skin Department, 9.15 A.M.  
**LONDON POST-GRADUATE COURSE.**—Bethlem Hospital: 11 A.M., Dr. Percy Smith: Alcoholic Insanity.

Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors." Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher." We cannot undertake to return MSS. not used.*

A MODERN SCIENTIFIC DISCUSSION.

"—Anims Cœlestibus Irra!"

*Miss Fanny (a gentle and most veracious child): "Yah, you cruel coward! you and your friends skinned a live frog!"*

*Master Victor (an industrious but very touchy little Boy): "You're a liar! The frog was dead, and you know it!"*

*Miss Fanny: "Boohoo! Whether it was dead or not, you've got no right to call names; 'cos I'm a girl, and can't punch your head."*

*Master Victor: "It's just because you're a girl that I can't punch yours! You should have thought of that before you called me a coward!"*

Punch.

*W. H. C.*—Assuming the correctness of our correspondent's statement that the appointment rests with the Home Secretary, the course he suggests would certainly be advisable, but we would advise him to make careful inquiry as to whether the appointment does not now rest with the County Council.

*Mr. Ralph Cann (Plymouth).*—The observations of our correspondent are not new. They have been made and described many years ago by Helmholtz, and he will find a very similar description of the phenomena in Jago's Entoptics (Churchill, 1863).

*Mr. C. J. Rawlings.*—An abstract of the address will be found in THE LANCET of Oct. 8th, 1892.

## "THE MEDICAL JOURNALS AND INFAMOUS CONDUCT."

The *Food, Drugs and Drink Journal*, while approving our protest against those who lend themselves to medical aid associations on undignified and ruinous terms, complains that we have no censure for men of eminence in the profession, who are always ready to give testimonials for "anybody's soap, cocoa, mustard," and every rubbishy, much-advertised article. We are not prepared to admit this charge. Let our contemporary give instances with details more carefully, and we shall not fail to say what we think. We are quite of opinion that there is too much readiness to write testimonials that greatly mislead the public, and that the evil needs strong treatment.

Mr. Edwin Hegan, M.B., B.Ch.—We do not know of any work on physiology which discusses the subject alluded to by our correspondent. But such a division might be made in several ways—as, topographically, into head, body and extremities; or, histologically, into nervous, vascular, glandular, osseous and muscular systems; or, embryologically, into tissues derived from epi-, meso- and hypoblast respectively; or, functionally, into organs of secretion, sensation, motion, support, digestion, reproduction, and the like.

D.P.H. Camb. will probably find all the information he requires in "Sewage Treatment, Purification and Utilisation," by J. W. Slater, published by Messrs. George Bell and Sons.

## CLERICAL INTERFERENCE WITH MEDICAL DUTIES.

To the Editors of THE LANCET.

SIRS,—Some two months ago I was called to a case of typhoid fever existing in ——. In the usual course I notified this disease to the medical officer of health of the district. The sanitary inspector called at the house, and amongst other directions instructed the inmates that they were not to send the only child (not the patient) to school, that none of the inhabitants of the house were to go to church, and gave a mass of other instructions, and finally left a certificate for me to fill up, to state when the patient had finished desquamating, so that disinfection could be properly carried out—all of which directions were of course very right and proper if it had been a case of scarlet fever and not typhoid fever, which it was notified in my certificate to be. I wrote to the medical officer of health pointing out this, and saying that I thought his sanitary officer must have made a mistake as to the nature of the disease. I received a courteous reply from him, agreeing with my letter to him, but not laying any blame on his officer, as was perhaps quite natural, and there I supposed the matter had ended. I am sorry to say I did not keep the medical officer's letter to me, but the above was the tenour of it. Judge, then, of my surprise when I received this morning the following letter (I may say that the case occurred in an adjoining parish and that I had never once seen the Rev. —, though I had heard his name before):—

[COPY.]

Oct. 28th, 1892.

"SIR,—I learn that you have been the medical attendant on a person named —, residing at — Farm, —, in the parish of —, during the latter part of last month; that you notified Dr. —, who in turn notified me (the italics are mine) on Sept. 19th last of the infectious character of the disease (typhoid fever) from which the said — was suffering; that you afterwards denied the fact of your having notified the medical officer of the district; and that you represented it to be impossible that I could have received a notification (the italics are mine), as none had been sent. Before any further action is taken in this matter I shall be glad to hear what you have to say.

"I am, yours truly,

—, Vicar of —.

"Dr. —."

[ANSWER.]

Oct. 20th, 1892.

"SIR,—As a matter of courtesy only do I take the least notice of your impertinent letter dated Oct. 28th, 1892. I deny your right in any way whatever to catechise me as to what I have done, or what I have not done in my medical capacity. I notified to the proper authority that a disease (scheduled under the Infectious Diseases Notification Act) existed at —, and therein fulfilled the duty required of me by the law; nor have I so far stultified myself as to deny what I had already recorded in writing and sent to the authority properly constituted for the reception of such intelligence. I decline to answer or in any way notice any further communication from you on this subject.

"I am, yours truly,

"The Rev. —, Vicar of —."

## "THE OWNERSHIP OF PRESCRIPTIONS."

To the Editors of THE LANCET.

SIRS,—Will you allow me (as a dispensing chemist) to point out to your correspondent, "H. S. F.," the fact that the druggist has no power to refuse to dispense any prescription presented to him if it is properly signed. I believe that every dispenser would prefer to dispense a fresh prescription than an old one repeatedly; the remedy rests entirely with the profession. The prescriber should write on the bottom of the prescription, "This prescription must not be dispensed after—," but this would have to be written in Latin, or the patient would probably tear it off as unimportant. It would then be an easy thing for the druggist to explain to the patient that the doctor did not intend any more of that medicine to be taken, and that he must go and consult him again.

I am, Sirs, yours faithfully,

Oct. 20th, 1892.

A. A. B.

## A NOTEWORTHY BEQUEST BY AN EDINBURGH DOCTOR.

AMONGST the legacies bequeathed by the late Dr. William Fullarton Cumming, Kinellan, Murrayfield, Edinburgh, is the following:—To the managers of the Royal Infirmary of Edinburgh, £600, but only on the condition of their undertaking to invest the same and apply the annual income thereof in the purchase of snuff and tobacco for the use of such poor patients, male and female, as may be admitted into the infirmary on account of fractures, dislocations, scalds, ulcers and other chronic maladies, and who have been addicted to the use of tobacco in any shape and are known to be in distress from the want of it; or the managers may use such part of the income as they may think right from time to time in the purchase of tea and sugar for the use of such of those patients as may prefer tea and sugar to snuff and tobacco. In a separate paper, in his own handwriting, Dr. Cumming says:—"In my youth I was a dresser in the Infirmary of Edinburgh, and often had occasion to witness, and always the desire to relieve, the distress arising from inability on the part of the poorer patients to provide themselves with a long-accustomed gratification; and having been for more than twenty years of my life a slave to the use of tobacco, I know how to feel for the suffering of those who, in addition to the irksomeness of pain and the tedium of confinement, have to endure the privation of what long habit had rendered in a great degree a necessary of life. To some the bequest will appear whimsical and eccentric. No votary of tobacco will be of this opinion. I have no wish to teach bad habits, but it is my desire that the bequest be strictly carried into effect."

*Inquirendus.*—It is useless applying to the Local Government Board for superannuation, unless the board of guardians have recommended it on the resignation of the medical officer. It is the best policy to sound the guardians privately upon the subject before resigning. The recommendation of the guardians is seldom refused by the Local Government Board. We trust in time to obtain compulsory superannuation for Poor-law medical officers of long standing.

Mr. John E. Allen.—We see no reasonable objection to the circular, if couched and distributed in a strictly private manner to *bona-fide* patients.

Mr. B. H. Thwaitc is thanked for his communication, but the subject of the paper and the analytical statistics therein have already been dealt with in our columns.

## "THE HISTORY OF QUACKS AND QUACKERY."

To the Editors of THE LANCET.

SIRS,—Your correspondent "A" will find, on turning to Defoe's "Journal of the Plague in London," in Nimmo's edition of Defoe's works, on pages 400 and 401, a very graphic description of *medical* quacks and their ways, given as none but Defoe could give. If "A" be not already aware of the fact, let me inform him that Defoe was born in 1691, and that he was but four years old when the Great Plague occurred. Moreover, the celebrated Dr. Mead was said to have been "taken in" by the work of Defoe, as the descriptions Defoe gives are so realistic that it is hard to believe he was not really present during the Plague and really heard the bellman's cries and saw the dead cast coming round. "A" will find quacks referred to in other parts of the work. *Apropos* of this subject, I find that Chambers's "Etymological Dictionary" states that the word "quack" is derived from the cry of the duck.

I am, Sirs, yours obediently,

LEONARD KIDD, L.R.C.P. Edin. &c.

George-street, W., Oct. 31st, 1892.

## A MÆDIEVAL REMNANT.

To the Editors of THE LANCET.

SIRS,—The following inscription, which is from a notice affixed to the portal of a doctor's residence at Trani, in Southern Italy, and may be found in Ross's "Land of Manfred," London, 1889, may interest your readers, and perhaps be of value to the scientists who compile the annual supplement to the British Pharmacopœia:—"Professor Ricca.—The said Professor Ricca will use for making his salvers live snakes and large serpents, wolves, bears, monkeys, marmots, weasels, and numerous other kinds of wild animals, alive and in good condition." ("Il medico Professore Ricca, per fare i suoi iunguenti, comperà serpenti e serpi grossi vive: lupi, orsi, scimie, marmotti, fa'ne e tante altre razze di animali selvaggi vivi e sani.")

I am, Sirs, yours faithfully,

London, Oct. 1892.

J. OFFORD, junior, M.S., B.A.

## "PECULIAR SYMPTOMS OF POISONING BY SANTONIN."

To the Editors of THE LANCET.

SIRS,—The case "M.R.C.S." reported in your last issue (p. 1081) does not apparently greatly differ from many of the cases noted in the Medical Digest, Section 307:4, or from the effects produced in one of my own children many years ago in Batavia, upon which occasion it was as much alarmed as "M.R.C.S."

I am, Sirs, yours obediently,

Boundary-road, N.W., Oct. 29th, 1892. RICHD. NEALE, M.D. Lond.

The Bradshaw Lecture

ON THE

SIGNS OF ACUTE PERITONEAL DISEASES.

Delivered before the Royal College of Physicians of London,

By SAMUEL GEE, M.D., F.R.C.P. LOND.,

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

MR. PRESIDENT AND GENTLEMEN,—Peritonitis is a word strictly anatomical, and relates to an affection of structure only. The structure affected is known by its ancient Greek name—"peritoneum"; the corresponding English term, "the rim or rim of the belly," has gone out of use, or is remembered by being found in old books, such, for instance, as the writings of those learned anatomists, Robert Burton and Phineas Fletcher, contemporaries of Harvey. The peritoneal structure has functions, no doubt, but they are so unimportant or so obscure that, however much they be disordered or suspended, no signs peculiar to the consequent disease can be discerned. This is the reason why the ancients, whose nosology was founded almost wholly upon symptoms or disordered functions, knew nothing about peritonitis as a disease of the peritoneum—in other words, peritonitis was not recognised before morbid anatomy began to be studied; nay, not until morbid anatomy had been studied for many years. In Morgagni, and even in Matthew Baillie, there is little or nothing about peritonitis—indeed, nothing about it under that name. Nor could anything be more natural than this state of opinion. When the abdomen was laid open, in a fatal case of peritonitis, it was not the peritoneum, but the intestine, the stomach, the omentum, all highly inflamed, that caught the mind's eye of these early anatomists; nor did they inquire which portion of those viscera was inflamed first and foremost. Hence the nosologist, Sauvages, invented the terms "gastritis," "enteritis," "mesenteritis," "metritis," "cystitis," to signify the inflammation of the respective organs as manifested by changes in their outer peritoneal tunic; and, from 1750 to many years onward, these words were much used, and always in the sense indicated. Sauvages invented the term "peritonitis" also, but he meant thereby inflammation of that part alone of the peritoneum which lines the abdominal walls and covers no viscus. No wonder that the word, while this was its meaning, was very seldom employed; no wonder that Cullen, who in his "Nosology," gives a place to peritonitis, excludes it from his *first lines*, saying that the disease, when existing alone, is hardly to be recognised and does not require any special treatment. This state of morbid anatomy, this failure to recognise the unity of peritonitis, faithfully reflected the state of anatomy in general. The peritoneum was known as being the outer tunic of the stomach, intestines and other abdominal viscera, but of the peritoneum as a uniform continuous structure, as a single organ, so to speak, anatomists, before the time of Bichat, had little or no notion. The study of puerperal fever led the way to more modern opinions. That disease had been known for many centuries, but by its symptoms only; one of the best descriptions of it, written from this point of view, is to be found in the works of our distinguished Fellow, Thomas Willis. He, in all likelihood, never examined a case after death, and he therefore deemed the fever to consist wholly of an infection of the blood, not secondary to any local inflammation. It was not until the middle of the last century that it came to be known by many that the abdominal viscera, or rather, their peritoneal surfaces, are inflamed in most cases of puerperal fever; and from this time onward one form at least of universal peritonitis was well known; but not known by the name "peritonitis"—that term had been invented, but was never employed—a fact which is proved by a story which John Hunter used to tell in his lectures. He said: "A man whom I tapped at the hospital died the third day. I said he died of the puerperal fever. This was smiled at in the hospital, and some were pleasant in remarking on the curiosity of a man being delivered; but a few months afterwards, another having the same fate, I convinced them, by dissection, that he had died of suppuration of the peritoneum, which

No. 3611.

we must admit to happen in puerperal fever." A great change of opinion, and a conversion to the modern conception of the peritoneum, is marked by the publication of Bichat's treatise on membranes in 1800. Henceforth the peritoneum is deemed by all to be not many portions, but a single whole. Discoveries are seldom made at a bound; the sunrise is foretold by the daybreak; and there were those who, before Bichat, had perceived the unity of the peritoneum; I refer especially to James Douglas and Johann Gottlieb Walter. Bichat was more than an anatomist; he was a great morbid anatomist; he had attained to modern doctrine with respect to peritonitis also. But what his early death—a death too early—suffered Bichat not to write was written by his disciple Laennec, whose "Histoires d'Inflammations du Péritoine," published in 1803, were the first essay on peritonitis conceived in the modern spirit. Here I will bring my preliminary history of opinion to an end.

It is not my intention to speak of the morbid anatomy of peritonitis, nor of its causes, a topic which is becoming more and more one of microbes and morbid poisons, for peritonitis also has entered the great class of parasitic, zymotic and virulent diseases. The changes which peritonitis begets in the living body is my theme. I am not so vain as to suppose that I can say anything which will be new to such an audience as this; all that I can pretend to do is to recall to your memories the facts of your own experience and to arrange, criticise and endeavour to explain those facts. *Ament meminisse periti.*

*Local signs.*—The chief local signs of acute peritonitis are three—pain, meteorism and ileus,—and to these I will, in the first place, direct your attention. But before I proceed I may remark that, with regard to the symptoms, both local and universal, of acute peritonitis, it would be possible to take the term "peritonitis" in the sense of any affection of the peritoneum, which is all that the word signifies, strictly speaking. The termination "itis" is a feminine adjectival suffix which has nothing to do with implying inflammation; peritonitis means no more than peritoneal, disease being understood. The symptoms of sudden inflammation of the peritoneum, of sudden hæmorrhage into the peritoneum and of sudden perforation of the peritoneum are essentially the same. However, I have not the slightest intention of using the word in any but its customary sense, and peritonitis shall mean, as it always has meant, inflammation of the peritoneum.

*Pain.*—Broussais speaks of pain as being the only pathognomonic sign of peritonitis. I fear it would be nearer the truth to say that there is no pathognomonic sign at all. Yet, however vague and uncertain a sign of disease pain may be, it often is, at the onset of peritonitis, our only guide to the locality of the affection, although an untrustworthy guide. The earlier physicians called the pain of peritonitis, colic; nor is it always easy, even in the present day, to distinguish colic from peritonitis. The symptoms associated with the pain do not always help. In some cases of mere colic (or intestinal pain), say lead colic, the abdomen is very tender to the touch, and the pain is not relieved, but is even increased, by firm pressure. Moreover, colic is sometimes a febrile disease, and for proof of this assertion I may again refer to lead colic; the temperature of some persons suffering from that disease will rise considerably and remain for days above the rule of health. The colic of indigestion is sometimes indistinguishable from an attack of peritonitis, until the threatening symptoms pass away with a free action of the bowels. But the most puzzling disorder of this kind which I have met with is the abdominal pain which sometimes accompanies the menses in young women. Pain, having all the characters of colic, is common enough about the menstrual period and causes no difficulty. Menstruation is not seldom a febrile process, and when this is all, we know with what we have to do. But when abdominal pain and fever are associated, when they precede the appearance of the menses by two or three days, when the patient shivers once or twice, vomits, lies with her knees drawn up, and when her abdomen becomes swollen, how can we at first have any doubt that she is suffering from peritonitis? Yet no sooner do the menses occur than all these symptoms disappear, and then how can we any longer believe that her complaint has been peritonitis? Not only does colic simulate peritonitis, but the reverse also is sometimes true, that peritonitis at the onset cannot always be distinguished from colic. The diagnostic difficulty may be met with, for instance, in peritonitis due to sudden perforation of a hollow viscus, especially the stomach or duodenum. In such

cases it often happens that the temperature of the body does not rise; and for some hours at least the pain has all the characters of colic pain, and there are no other distinctive signs. Still it may be that in contrasting thus the pain of peritonitis with the pain of colic we are seeking for a distinction where there is no real difference. Indeed, it is highly probable that the earlier physicians were often right, and that much of the spontaneous and paroxysmal pain of peritonitis is due to colic—that is to say, to vermicular contractions of the intestines much more powerful than usual. Surgeons tell us that when they open the abdomen in order to remove an ovary the intestines are seen to be at first in very active movement; and that these movements may be painful is proved by what we sometimes observe in intestinal tympanites, when the peristaltic contractions of the bowels can be seen through the abdominal walls, each contraction being attended by an unnatural sensation or by actual pain. Moreover, surgeons say that they can handle, cut and scratch the stomach or intestines of a man who is quite sensible and not cause in him any sensation of pain; but we cannot go so far as to affirm that an inflamed peritoneum may not be extremely sensitive to painful impressions. As to tenderness upon pressure of the abdomen, is it not a mistake to suppose that it is pressure upon the peritoneum alone which brings forth the pain? The skin also is tender, and is sometimes tender to the gentlest touch. In bygone days I have attempted to shave the head of a patient suffering from acute meningitis and have been compelled to desist on account of exquisite tenderness of the scalp. No question of pressure upon the membranes of the brain can arise under such conditions. Indeed, tenderness of the skin is apt to follow great pain of any underlying part. I have already remarked that simple colic may be accompanied by great tenderness on pressure; and I commend the consideration of these facts to those who find a difficulty in believing that leeches or blisters applied to the skin can possibly affect a deeply-seated part with which the skin has no obvious connexion.

**Meteorism.**—Leaving the topic of pain, I now pass on to the other local signs of peritonitis—namely, meteorism and ileus. The pain is in great part intestinal; meteorism and ileus are wholly such. The pain is in great part due to intestinal spasm; meteorism and ileus are due to intestinal paralysis. The hollow viscera with muscular coats are the only viscera which are directly affected by the peritoneal inflammation, and this affection takes the form of spasm or paralysis. Patients with peritonitis are often unable to pass their urine, whether from paralysis of the bladder or from inability to start the reflex act may be open to question; the latter is probably the more usual cause. But about the intestinal paralysis there can be no doubt. It manifests itself in its earlier and slighter degrees by meteorism or acute flatulent distension of the bowels. I do not speak of that peritoneal meteorism which is due to the escape of air into the peritoneal cavity in consequence of rupture of some part of the alimentary canal, but of that intestinal meteorism only which is secondary to peritonitis. Intestinal paralysis is no longer a matter of inference. Abdominal section nowadays often gives surgeons the opportunity of seeing how intestines which, when first exposed, were in active movement afterwards become exhausted and lie limp and motionless. This intestinal paralysis is not continual or not universal, for in patients whose abdominal walls are thin vermicular movements of the intestines, either spontaneous or produced by handling the abdomen, can be seen sometimes in spite of very great meteorism. But this is an exception to the rule. Usually no intestinal movements can be seen, and probably none occur or else they are too weak to show themselves. So we may suppose that the flatulent distension is due partly to relaxation of the intestinal walls and partly to weak peristaltic movement insufficient to pass the flatus onwards, a condition closely resembling constipation. This torpid meteorism, I just remark in passing, may be attended by great and constant pain—a fact which seems to show that the pain of peritonitis is due not altogether to colic or painful intestinal contractions, but partly to the inflamed peritoneum itself. Another proof that the intestines are not so utterly paralysed as might at first seem likely, or that the large intestine at any rate escapes, is afforded by the fact that natural defecation or even diarrhoea will accompany acute peritonitis. This was so in the epidemic disease which bereaved our College of a Fellow whose name no doubt remains in the memory of many here present; I refer to Dr. Francis Anstie. You will allow me briefly to repeat the story, which may be known to all. Fifty-two girls in the Royal Patriotic

School at Wandsworth were attacked within one week by a disease characterised by two main symptoms—namely, by lipothymia, with coldness and lividity of the face and limbs, and by great pain in the abdomen, which was tender also to the lightest touch. Four children died, and dissection of the bodies revealed peritonitis. One fatal case suffered from diarrhoea with rice-water stools, and was examined by Dr. Anstie. He pricked his finger and died six days afterwards, poisoned as if by a snake-bite. A remarkably similar epidemic, which occurred in a charity school for girls at Edinburgh, called the Merchants' Hospital, is described by Abercrombie. Peritonitis by itself would probably always be attended by the constipation of paralysed intestine; and surgeons note great constipation in cases of peritonitis following abdominal section. When diarrhoea concurs modern doctrine would lead us to infer the coexistence of an infection of the intestinal mucous membrane, especially that of the colon.

**Ileus.**—A higher degree of intestinal paralysis is marked by the state called ileus, a word which has been sufficiently constant in its meaning from the earliest times. It denotes disorder of an intestinal function—namely, of the peristaltic function—and implies inability on the part of the intestine to propel its contents. The kind of ileus which concerns us here is that which is due to inflammation of the intestines, or enteritis. I have already remarked that the term "enteritis" originally meant an inflammation of the peritoneal coat of the bowels. It was Broussais who most unwarrantably perverted the meaning of the word, and who used it to signify an inflammation of the mucous membrane of the intestine—one out of many instances showing the degree to which corruption of our technical terms has been carried. They who continue to use the word "enteritis" in its original sense do no worse than follow the example of Pemberton, Abercrombie, Graves and Watson. For those who desire a name to express inflammation of the intestinal mucous membrane the terms "eso-enteritis," "muco-enteritis," "enteritis mucosa" have been invented. The sign of ileus is vomiting becoming fecal. The father of physic has well described the course of events, the matters vomited being first mucous, afterwards bilious, and lastly fecal. Until the vomit became fecal, or at least porraceous (meaning thereby an appearance like chopped grass or spinach), it is impossible to affirm the existence of ileus. The concurrence of constipation is no help, and indeed, on the other hand, fecal vomiting may be attended by the evacuation of small loose stools, resembling in colour and other respects the pale, uniform, pasty intestinal contents found in cases of mechanical obstruction. I need not stay to bring proof that stercooral vomit may be due to obstruction in the ileum; and thus the question, formerly so much debated, of possible reflux through the ileo-cæcal valve loses its interest. Nor need I discuss the mechanism of fecal vomiting, or say more than that there is no evidence of inverted peristaltic movement of the intestines. If enemata ever become emetic, as Sydenham says they do, it can only be by absorption into the circulating blood, just as vomit may smell of turpentine after the use of that drug in a clyster. So that pain and the signs of intestinal paralysis are the only local evidences of acute peritonitis. It were much to be wished that the disease afforded physical signs such as are usually present in chronic peritonitis. Purulent discharge from the navel in acute peritonitis (just as in the chronic disease) indicates a circumscribed peritoneal abscess; in acute peritonitis the abscess is mostly connected with disease of the appendix vermiformis. I do not know that a suppuration of the whole peritoneum ever points at the navel or elsewhere; a form of disease so virulent as this kills the patient before the collection of pus has time to point. We open these local abscesses freely, and with much success; but with regard to total peritoneal suppuration, I will adopt John Hunter's words without change: "How far in such cases it might appear desirable to make an opening into the abdomen and throw in warm water repeatedly to wash away the matter I will not undertake at present to determine."

**Fever.**—Let us now pass on to consider the remote or universal effects of peritonitis; and first of fever. There is no symptom more uncertain than this, the temperature being sometimes high, and reaching 105° or more, usually but moderately raised; whilst in other cases there may be no fever at all, so far at least as can be judged by a thermometer in the mouth or axilla. This apyrexia is a remarkable symptom when present, as it sometimes is, from first to last in peritonitis the most intense and fatal. We are tempted to speculate upon the cause of so strange a phenomenon.

Whether an ordinary febrile poison be not produced by the inflammation, or whether an extraordinary febrile poison be produced, at present we cannot do more than note the fact. *Apæxia* sometimes becomes *algidity*—an important sign of the *lipothymial* state to which I shall soon refer.

*Puridity*.—More certainly due to an infection of the blood are the *putrid* or *septicæmic* symptoms which sometimes happen. When we bear in mind what Bichat pointed out, that the peritoneal cavity is a lymphatic sac with a most extensive absorbing surface and an extraordinary power of absorption, the wonder is that these symptoms do not occur oftener. I will illustrate this form of disease by the case of one of our students at St. Bartholomew's Hospital. He was running along the street and got a heavy fall, which was the only discoverable cause for the acute peritonitis that occurred within forty-eight hours. Delirium and diarrhoea were associated with the abdominal pain and vomiting of the first few days. On the sixth day he complained chiefly of pain in his joints; his feet and one shoulder were swollen and excessively tender. The skin over the feet, wrists and ankles was red in patches. His urine was highly albuminous, but no blood-corpuses or casts were found in the sediment. The diarrhoea continued; he lay in a state of typhomania—that is, of delirium with consciousness much impaired. He had a greater tendency to chills and occasional shivering than is usually met with in cases of peritonitis; the temperature varied between 102° and 105°, until a few hours before death, which occurred on the eighth day. At the post-mortem examination nothing was found but peritonitis and its results; its cause was not found.

*Lipothymia*.—I will next speak of that marked failure of the vital functions (that is to say, of the circulation, respiration and body heat) which very often accompanies peritonitis. It is a matter for surprise and regret that we have no term in common use to express this set of symptoms. No English word being precise enough, I suggest that we resuscitate the Greek word "*lipothymia*," to denote *defectio animæ*, this failure of the vital constitution, whether it be attended or not by *lipopsychia*, *defectio animi*, or failure of the animal constitution marked by coma, delirium, or both. Sudden *lipothymia* is syncope or swooning; syncope due to injury is shock. *Lipothymia* is manifested by a small, weak and sometimes irregular pulse, by weakness of the heart sounds, by shallow breathing, by lividity with pallor (deathly paleness), and by *algidity* or failure of the body heat—at least so far as the skin is concerned; the inner heat, as measured in the rectum, may or may not fail to a proportionate degree. In peritonitis (apart from perforation) *lipothymia* sometimes marks the whole course of the disease (witness the Wands-worth epidemic, to which I referred a short time since); and when to lividity, coldness of skin and a weak small pulse are added diarrhoea, with watery stools and suppression of urine, the resemblance to cholera is great indeed. But more frequently *lipothymia* occurs only towards the end of life, and then it may assume, so far as the body heat is concerned, the form of *lipyria* (another ancient word which might be revived with advantage)—that is to say, while the skin, especially of the limbs, is quite cold, the temperature of the inward parts, as measured by a thermometer in the rectum, is much above the normal; it may be 105°—a very bad prognostic sign in all acute diseases, and a plain proof of the extreme weakness of the circulation. Another sign which sometimes attends this final *lipothymia*—this mortal agony or struggle with death—a sign which has attracted the notice of physicians from the earliest times—is the disappearance of pain and suffering whilst the patient remains perfectly conscious; yet all the symptoms of vital failure persist, and he only whose attention is fixed upon the local signs to the neglect of the prognostic condition of the whole patient can be surprised by what will seem to be a sudden and unexpected death. It were curious to inquire into the causes of this cessation of pain, whether it be due to cessation of cramp, whether an anodyne poison be produced in the course of the disease, whether the *lipothymia* arrests the nutrition of the nerve endings, or whether the sensorium for pain be similarly affected; but I will say no more than to remind you, Sir, that an honourable predecessor of yours in that honourable chair—Sir Henry Hallford—once read before the College an essay dealing with this very topic. Still more remarkable, although much less common, is the case of peritonitis attacking a healthy person, *lipothymia* supervening in the course of a few hours from the beginning, and any local signs of abdominal disease disappearing at the same time. The patient when first seen makes little or no complaint of the abdomen; it is not

swollen and can be pressed deeply without causing pain; but the skin is cold, the heart beats very frequently, no pulse can be felt at the wrist, the respirations are very frequent, and the secretion of urine is suppressed. The mind is affected little or much. The patient dies on the first or second day of illness. At the post-mortem examination acute peritonitis is found, but not necessarily perforation of the peritoneum or disease of any other abdominal structure.

*Facies*.—The last sign of acute peritonitis which I shall notice is that afforded by the look and expression of the face. These signs and such as those which constitute the prognostics so much trusted by the earlier physicians can be learnt in no other way than by a long familiarity with disease. If I allude to the countenance which still goes by the name of "*facies Hippocratica*," it is only to remark that Laennec has endeavoured to walk in the footsteps of his great predecessor and to depict an expression of face often seen in peritonitis and other severe abdominal diseases. This peculiar look, which he calls "*face grippée*," is due chiefly, if not wholly, to the features being drawn upwards, so that the forehead is more or less wrinkled, and the naso-labial furrows are drawn inwards and upwards towards the root of the nose and inner canthi of the eyes. I have compared Laennec's verbal picture with the living patient, and have found it to be true to nature—but not universally true, not present in every case of acute peritonitis. Indeed, I think that the *face grippée* denotes abdominal pain, and that it usually disappears with the pain, although the disease continues. But we must admit that the local suffering and signs of disease may be very small, and yet the onset of peritonitis be denoted by a profound change in the expression of the patient's features. Surgeons remark this change when an operation is followed by peritonitis; physicians, also, when a perforation occurs in the course of typhoid fever.

*Latent peritonitis*.—Now a few words concerning latent peritonitis. I have already spoken of peritonitis which is latent in respect of its local signs only; peritonitis in which universal signs of disease—those, namely, of alarming *lipothymia*—predominate to the exclusion of abdominal symptoms, the patient being killed in a day or two as if by the operation of a powerful venom. But peritonitis may be altogether latent, and manifested neither by local nor by universal symptoms—a form which is deuteropathic, intercurrent in the course of other serious disease, such as ascites, renal dropsy, empyema, pyæmia, or typhoid fever, the peritoneal inflammation being revealed by the post-mortem examination only. What surprise we may feel at this latency diminishes when we reflect that the signs of peritonitis have little or no relation to the peritoneum, but depend upon disorder of other viscera, adjacent or remote. Suppose the onset to be marked by vomiting, what is there distinctive in this? In what disease does vomiting not occur? Is not the stomach the great sympathiser with distress in any part of the body? Add some pain in the abdomen, and how does this help us? Possessing no direct physical signs of peritonitis, and being compelled to rely upon indirect disturbance of the functions of other viscera (for the peritoneum itself has no manifest functions), we cannot expect to discover the presence of peritonitis in cases such as these.

*Types*.—After analysing the symptoms of peritonitis I might endeavour to arrange them so as to form concrete pictures of patients suffering from that disease; but I will say no more than this, that according as one or other symptom prevails, so does the appearance of cases of peritonitis differ, and the differences are so great that we have to admit divers forms or types of the disease. We cannot manage with fewer types than three—namely, peritonitis characterised by pain, or by ileus, or by *lipothymia*; for peritonitis discovered only after death cannot be admitted to be a form of disease as looked at from my present point of view. A given case of peritonitis is by no means necessarily constant to one type throughout; for instance, painful peritonitis may pass into ileus, and, moreover, the local and universal symptoms may be variously mixed. But the only reason I have for referring to facts so obvious is to be assisted by these types in comparing the signs of acute peritonitis with the signs of other peritoneal affections, which I will now proceed to do.

*Chronic peritonitis*.—Peritonitis, which is essentially chronic in its course, sometimes sets in suddenly, and thus resembles at first the acute disease. This is often observed in the commonest kind of chronic peritonitis, the tuberculous, when, as I suppose, a sudden infection of the peritoneum takes place. The forms assumed by this acute onset of tuber-

culous peritonitis are the same as those I have just discussed. That most often met with begins with pain, vomiting and sometimes diarrhoea, and is followed in a few days by meteorism, which may become very great. Lipothymia in a high degree may attend the choleric symptoms. The least common type, which assumes the form of ileus, deserves especial notice on account of its close resemblance to mechanical obstruction of the bowels—a resemblance so close that abdominal section has been performed in such a case under the notion that the patient was suffering from a strangulated hernia.

*Hæmorrhage into the peritoneal sac* is another form of peritoneal disease in which we meet with these same types. The painful form is well illustrated by the case of "a woman, aged twenty-nine, who was brought to the hospital in a most alarming condition, although her illness had not lasted longer than a few hours. She had been suddenly attacked by great pain in the lower part of the abdomen, and the pain had steadily increased. She had the *facie grippée* and was deadly wan, her breathing was short and frequent, interrupted by hiccough, her pulse hurried and very weak, her abdomen distended and tender. She died within forty-eight hours from the beginning. At the post-mortem examination there were found in the peritoneal cavity nearly three pints of liquid blood which had come from one of the Fallopian tubes; no peritonitis." How peritoneal hæmorrhage may be attended by ileus is shown by the case of a man, aged twenty-two, who was admitted into St. Bartholomew's Hospital in an extreme state of shock following a fall off the tailboard of a van in motion. He complained of great pain at the pit of the stomach, and soon after the injury he began to vomit incessantly. On the second day the vomiting continued to be very frequent. He had a great desire to defæcate but passed nothing; his abdomen was very hard and tender; the urine was suppressed; his temperature was 99°6'. On the third day he was worse. Abdominal section was performed. The peritoneum was found to be full of dark liquid blood; nothing more was discovered. On the fourth day he died; the blood came from a rent liver.

*Perforation of the peritoneum.*—A much more common acute affection of the peritoneum is that which I mention in the last place—namely, perforation or rupture of the wall of a canal or cavity or hollow viscus, and escape of its irritant contents into the peritoneal sac. When we seek to classify cases of this kind we come upon the three or four types of which I have already so often spoken—the type characterised by pain, or by ileus, or by shock, and the latent type. But before depicting them let us ask whether peritoneal perforation yields any peculiar physical signs? None, unless peritoneal tympanites ensue; and this depends, of course, upon the perforated cavity, whether it contain air or not. In the case of peritoneal tympanites, physical examination usually affords more or less probability of the presence of air in the peritoneal sac, but seldom an absolute certainty. The distension of the abdomen is often very great, and greater in perforation of the intestine than of the stomach; when the distension is very great, the skin is tense and shining to a degree seldom seen in intestinal tympanites. Visible coils of intestine or vermicular movements are decisive evidence of intestinal tympanites. Absence of the liver dulness to percussion is a useful, but not altogether trustworthy, sign of peritoneal tympanites; for when the intestines are extremely distended with air they may come to lie between the liver and abdominal wall in front, and I have known this to happen even when the liver was enlarged to twice its natural size. On the other hand, adhesion of the liver's convex surface will obviously prevent the disappearance of its percussion dulness, even though the peritoneal cavity be full of air. The signs afforded by auscultation are less important, because they are common to all great accumulations of air within the abdomen, whether contained in the stomach or intestines, or free in the peritoneal cavity. The chief sign is the bell sound discovered by Laennec. In his "Auscultation Médiate" he says that by percussing lightly, and at the same time applying the stethoscope near by, we shall hear a silvery resonance—clearer, he thinks, in peritoneal than in intestinal tympanites. I cannot do more than just mention the other auscultatory signs of a large air-containing cavity, and which are sometimes present in peritoneal tympanites—namely, an amphoric quality in the respiratory sounds heard over the abdomen, metallic tinkle, and succession splash. A valuable sign is yielded sometimes by an escape of air into the cellular membrane of the abdominal walls; this fact, also, is alluded to by

Laennec ("a sort of dry crackling is felt upon pressure," he says), and is, taken together with the signs aforesaid, peculiar to peritoneal tympanites as contrasted with the intestinal; or the subcutaneous emphysema may be still more extensive. To conclude this topic of physical signs, I will remark that, although their presence is a great help to diagnosis, their absence proves nothing. Perforation of a part of the alimentary canal (for instance, the appendix vermiformis) may occur, may be followed by acutest peritonitis, and yet may be unaccompanied by peritoneal tympanites; nothing escapes from the rupture but offensive and poisonous pus.

With respect to the symptoms of peritoneal perforation, all cases may be referred to the four types so often spoken of—those characterised by pain, or by ileus, or by shock, and those not characterised at all, the disease being latent—latent, that is to say, so far as concerns the diagnosis. First of perforation characterised chiefly by pain. A lady had niled for some time from pain in the stomach and the side, but she seemed to be otherwise in good health. One day after dinner she complained several times of pain; she drank some succory water as a stomachic, and, putting the cup down with one hand, with the other she pressed her side, and said in a voice which betokened much suffering: "Ha! what a stitch in the side; what pain; I cannot bear it." Speaking these words she flushed, and a moment afterwards turned pale, with a wan lividity which astonished everybody. She kept crying out and begged to be carried away, for she could no longer hold up. Supported by the arms of others, she managed to walk, but with difficulty and bent double. Put to bed, she cried out more than ever that the pain at the pit of the stomach was past belief; she tossed from side to side. A physician was fetched, who pronounced her complaint to be colic and prescribed suitable remedies; but the pain continued; she said that her suffering was greater than could be conceived, and that she would die. All this occurred in less than half an hour. Whatever she swallowed made her retch; she brought up only a little mucus mixed with food. The efforts to vomit and the excessive pain threw her into a state of exhaustion which resembled repose; but she told the bystanders not to deceive themselves, that the pain was as great as ever, and that she had no strength left to cry out. She heard someone remark that she was easier, and she said; "That is so far from being true, that were I not a Christian I would kill myself, so great are my sufferings." It is wrong to wish evil to any," she added, "yet I would that somebody could feel for a moment what I feel, so as to know what my pain is like." Her pulse became imperceptible (*retiré*), her limbs cold. Her friends anxiously asked if nothing more could be done; they suggested a score of remedies, and, at last her physicians, in sheer desperation, made an attempt to bleed her, but the blood would not flow. They gave her some broth, for she had taken no food since dinner. She no sooner swallowed it than her sufferings (if not her pain) increased; she complained that her stomach was filling up. Death was painted on her face; the last struggle was short, and after two or three convulsive movements about her mouth she died nine hours from the beginning of her illness. Would you not suppose that I have set before you a living picture in words, taken from the pages of a modern Aretæus or of Sir Thomas Watson? or have you already recognised that I have been reading an account of the last hours of King Charles I.'s daughter, Henrietta, Duchess of Orleans—an account written by one of her ladies in waiting, Madame De La Fayette, 150 years before ulcer of the stomach was discovered, so we may say, by Cruveilhier? That the patient died from perforation of such an ulcer was proved by examination post mortem, although her physicians did not understand what they saw, and it was left for Littré to explain the real nature of her illness. I have always thought that reports of the kind just read, drawn up at the bedside by persons of keen intelligence, but with no medical knowledge, are of great value. Such reports are true to Nature, for the reporters have no preconceived notions of discolour and distort the appearances of things. Moreover, these observers see the sufferer and nothing else; but we physicians, on the other hand, in our eagerness to discover abstract signs of disease and to arrange them into that wholly artificial notion which we call the diagnosis, are apt to overlook the patient. The physicians of Madame said that she was suffering from colic, and that a wretched pulse and cold limbs such as hers were common in that disease. I likewise have stood by a patient writhing under the throes consequent upon perforation of the stomach or duodenum, and have asked myself whether there was anything either in the pain or its con-

comitants which might not occur in intestinal colic, and have been compelled to admit that there was nothing. This difficulty in diagnosis is not to be wondered at if the pain be, as is very likely, in great part due to cramp or painful spasm of the intestines and stomach and perhaps of the abdominal walls also. Yet our diagnosis may reach a high degree of probability under such conditions as these. The ruptured organ being more often either stomach or duodenum than any other; there may have been some forewarning symptoms of ulcer of one of those parts, the perforation occurring suddenly, so does the pain, and especially after a full meal or an effort or both. The very acid contents of the stomach poured into the peritoneal cavity are excessively irritant and the pain is violent in proportion, being far beyond the pain whereof the sufferer has had any experience or conception. The abdominal walls are contracted, tight, and hard, and often very tender. The pain will continue without remission to the end, or will cease altogether, or will only diminish—as I said when speaking of acute peritonitis. The associated symptoms may or may not assist the diagnosis. Vomiting—often present—is sometimes absent. Some have thought that it is absent in perforation of the stomach especially, but the exceptions to this rule, if it be a rule, are many and of both kinds—namely, rupture of the stomach attended by vomiting and rupture of a part not stomach, yet unattended by vomiting. Peritoneal tympanites will ensue if gas escape into the abdominal cavity; but gas does not always escape, even when some part of the alimentary canal is ruptured. Shock attends the rupture, and usually the lipothymia persists to the end. When perforation occurs in the course of a febrile disease defervescence is often a marked sign of shock. Suppression of the secretion of urine is common, and seems to be sufficiently explained by the vomiting and the lipothymia, and their necessary consequences—defective absorption and secretion.

The second kind of perforation—that characterised by ileus—is less common, and occurs especially in disease of the appendix vermiformis. The discharge of virulent offensive matter into the peritoneal sac seems to stun the intestines; they neither feel nor move. A woman aged twenty-two was admitted into St. Bartholomew's Hospital on March 8th. She had taken, on the 5th, jalap and castor-oil to relieve her habitual constipation. The bowels acted soon afterwards three times. Otherwise she was, so she and her friends averred, in perfect health and quite free from pain or indications of disease in the abdomen or elsewhere. Her menses, due on the 5th, did not appear. On the 6th vomiting began, and it continued at intervals up to the time of admission. The bowels had not acted. She was admitted on the evening of the 8th, and one of my surgical colleagues, who happened to be at the hospital at the time, came straight to my house and told me that a woman with obstruction of the bowels had just been sent in to be under my care, and he thought that the question of operation arose. We obtained the assistance of another surgeon and went to see her. We found a woman with no look of suffering, with a warm skin, a temperature of 99° 2' in the armpit, and with no symptoms of failure of the vital functions unless indicated by a pulse of 144, which was, however, by no means weak or small. The abdomen was fat and moderately distended, the muscles were tight, but there was no tenderness excepting about the right loin; the right iliac fossa was carefully examined, but nothing could be felt. Examinations *per vaginam*, *per anum*, and for hernia detected nothing wrong. An enema had brought away fæces. She vomited dark green liquid without smell. The urine was scanty; it contained a trace of albumen, was turbid with scaly epithelium and highly granular cylinders like renal tube casts, but there were no exudation corpuscles. The abdomen was opened; thin purulent liquid escaped, the small intestines were distended and purplish brown in colour. Examining the appendix vermiformis, we found a sloughy hole at its insertion into the cæcum, the rest of the appendix much dilated, its lining membrane ulcerated and granular throughout, the outer surface covered with lymph. She died two or three hours after the operation. Nowhere was there any anatomical obstruction of the bowels.

Between this form of disease and painful febrile peritonitis there are all possible varieties in respect of association of symptoms, the ileus being attended by more or less pain, tenderness, and fever. Peritoneal tympanites is often absent, any distension of the abdomen being due to acutest peritonitis, to intestinal tympanites, and inflammatory liquid effusion.

The third kind of perforation is characterised by shock. In some cases, particularly in rupture of the stomach or duodenum, the shock kills within a few hours, and may be justly compared to the effect of a blow upon the pit of the stomach, though why the shock of abdominal injury should be so especially profound I will not undertake to explain. In other cases the patient lives a day or two, yet never rallies. A man, forty years of age, who was under treatment for a chronic ulcer of the stomach, became suddenly, at eight o'clock one morning, pale, pulseless, and delirious (lipopsychia); he had evidently undergone a great shock. Throughout the day he continued to be delirious; consciousness never fully returned. Considerable reaction took place; his skin became hot, his pulse full and frequent; he retched a little, but did not vomit. The same night he became comatose, and so died at eight o'clock next morning. I regret being unable to say whether the urine was suppressed or not. On examining the body the ulcer was found to involve the pylorus and to have perforated on the duodenal side thereof. The contents of the stomach were in the peritoneal cavity, but there were no signs of peritonitis, neither excessive vascularity nor exudation of lymph. This kind of perforation closely resembles other abdominal diseases in which lipothymia predominates. You, Sir, have remarked how perforation of the duodenum will simulate Asiatic cholera in its algid stage; the physicians who attended the Duchess of Orleans came finally to the opinion that she died of cholera morbus; and Dr. Wm. Sedgwick has discussed this topic very fully with especial reference to the suppression of urine.

Lastly, the perforation may be latent; that is to say, unattended by any symptoms adequate to the diagnosis. Not that symptoms are utterly wanting; this is seldom the case; there are more or fewer of those so often mentioned—pain, vomiting, lipothymia and the rest—but they are rendered obscure by occurring in the course of a disease marked by no less serious disorders. The contrast between a person when in good health and when suffering from perforation of the peritoneum is great indeed; but when a patient has been exhausted by four or five weeks of severe typhoid fever, the occurrence of perforation may be a comparative trifle so far as symptoms are concerned; a little pain in the abdomen, a little vomiting, attracts no attention. Or there may be no pain, no tenderness, no vomiting; nothing but a sudden defervescence. Or, again, a change in the patient's look is sometimes the chief sign. During a state of typhomania, in particular, the gravest intercurrent lesions often happen unsuspected. But perforation, latent so far as symptoms are concerned, will sometimes yield one or more of the physical signs of peritoneal tympanites. For instance, in the later stage of typhoid fever, a rapid and great distension of the abdomen, such as to stretch the skin and make it shine and attended by disappearance of the liver dulness to percussion, is a tolerably trustworthy token of intestinal perforation, and is sometimes the only token. The liver dulness may disappear before the abdomen becomes distended.

*Incision for the purpose of diagnosis.*—To conclude by referring once more to puncture of the peritoneum as a means for ascertaining the presence of inflammatory effusion. A small incision would seem to be justified by conditions such as these: First, the patient is suffering from acute peritonitis, and the indications of poisonous infection of the blood are becoming more and more marked; or, next, there are reasons for believing that perforation of the peritoneum has occurred. In either case, unless we can bring relief, the patient must die. A small incision will not make him worse; nay, to drain the peritoneal cavity affords a chance of recovery; the only objection lies in the natural dislike to an operation, however small.

I wish I could believe that chloroform sleep did no harm, but I fear that this drug has a depressing effect upon persons suffering from acute peritonitis. However, suppose a small incision made, and we find that the peritoneum contains pus or air, beyond simple drainage two further courses lie open to us; we may follow John Hunter's suggestion, and wash the abdomen out with warm water, a proceeding more serious than simple drainage, or we may enlarge the incision and search for the cause of the peritonitis, a proceeding highly dangerous, for you will, I think, agree with me when I say that operations of this kind have seldom any other effect than to hasten the patient's end. A simple puncture, if it does not save the patient's life, will at least bring the satisfaction of knowing that the nature of the disease has not been misunderstood

## THE ETHICS OF OPIUM AND ALCOHOL.

THE ANTI-OPIUM CIRCULAR TO THE MEDICAL PROFESSION OF GREAT BRITAIN AND IRELAND.

By F. J. MOUAT, M.D. EDIN., F.R.C.S. ENG.,  
LATE LOCAL GOVERNMENT INSPECTOR.

"The falsehood of extremes."—TENNYSON.

THE Anti-opium Circular was issued in 1891, and a copy of it was sent to me. After careful perusal it appeared to me to be so inaccurate, sensational, and undeserving of serious notice from a professional standpoint that I put it aside. I subsequently had to notice it, and denounced it as a most "mendacious production." I have, in consequence, been requested to state on what grounds I based my charge, and this I shall now proceed to do, another copy of the paper having been courteously sent to me by one of the signatories, together with a list of the signatures to the circular.

The document commences by stating that "two things are sought: one that the Government of India should cease to foster the cultivation and sale of such a drug as opium for mere purposes of revenue; the other that the drug should be dealt with throughout India by classing it among the poisons and having it sold as such." These recommendations were formulated in four propositions, on which the medical profession was requested to express an authoritative opinion. Each of these I shall consider separately, before I conclude my reply to the challenge.

The above conditions conclusively render it an Indian and medical question; hence I shall treat it strictly as such, all collateral conditions notwithstanding. Indian questions, particularly those which refer to the actions of its Government and their influence upon the vast populations ruled by it, necessitate personal knowledge and experience only to be acquired by residence in India. Yet I find, in examining the signatures to the paper, that three out of the four gentlemen who signed it acquired their knowledge and experience of the drug in China as medical missionaries, and one only was a direct representative of India. It is needless to say that India and China have nothing in common as to their governments, ethnology, manners and customs, and all the collateral conditions which enter into the lives of the vast populations inhabiting them. There is no comparison possible between conditions so absolutely different. The gentlemen from China having signed and put forth a statement based upon an entire lack of personal acquaintance on their parts with the question as respects India in its fiscal, physiological and social relations, their opinions are not, in my opinion, entitled to be treated as authoritative in the determination of the views they advocate. I have searched in vain through the list of signatures, printed as a declaration of opinion, for a single leading representative of the medical profession in India as a supporter of the views contained in the Circular. It was also, I think, an unfortunate omission not to intimate, in connexion with their signatures, the *locus standi* in the arraignment of the Government of India, of the medical missionaries of China.

The medical profession itself is not, I submit, a fit tribunal to pronounce judgment, even from a professional point of view, on the question as contained in the appeal submitted. Beyond singularly erroneous statements of the evil influences said to be caused in India by the manner of dealing with the opium provided for its subjects, there is not a particle of medical or physiological proof adduced in support of those statements, as I think I shall be able to show. When there is tacked on to the statement of one opium cultivator demoralising a whole village, "being as true of India as of China." I cannot consider it as authoritative until the name and position of a single village so circumstanced are produced. To test the assertion I submitted it to an officer of the opium department who has served in that department for twenty-one years, and who was at home on furlough. He is in charge of the Gya and Tetah district, which is 345 square miles in extent, has 31,000 acres under poppy cultivation, yielding 5000 maunds of opium, and employs a body of 130,000 cultivators. During the whole of his service he has not seen a single opium drunkard either at the time of weighing, or in the district, and asserts positively that crime connected with opium is unknown among them, and that the most orderly villages in the district are those occupied by the opium culti-

vators or in their vicinity. The cultivators themselves are mostly confined to three castes of Hindus who never touch opium; and none of the cultivators can sell any opium surreptitiously to the inhabitants of the villages, for they are too poor to purchase it. The alienation of any portion of the crop would, moreover, be at once detected when the outturn is weighed and paid for. The officer in question has authorised me to make use of his name if I think fit.

Another statement equally open to question is that "the Government of India having already reduced the extent of the cultivation of opium by 100,000 acres, which was done neither at the call of, nor with any remonstrance from its people, but solely in connexion with the fluctuations of its trade with China, there is no question of its power to put down the cultivation over the remaining 400,000 acres now occupied with the poppy, just as easily as it put it down over the 100,000 acres. It is simply a question of revenue." It is to be regretted that any officer who has served in India should so thoroughly misunderstand the real bearings of the question. The Government of India could no doubt, if it were sufficiently ill advised to do so, exercise an overpowering despotism over any social proceeding of its own subjects; but there has never existed in any history with which I am acquainted a more thoroughly conscientious ruling power in dealing with the wants and wishes of those subjects, and in respecting their religious beliefs, habits and customs. In its fiscal and financial proceedings it is guided by other considerations which it would be absurd to discuss upon such grounds as are contained in this polemic. The component parts of the Indian empire have so few interests in common, and the people are so absolutely unacquainted with all combined action for political purposes, as to render the mere mention of the matter a crucial test of the unwisdom of its suggestion.

Now, how far, in what sense, and for what purpose does the Government of India foster the cultivation of opium for the use of its own subjects? Certainly not for the mere purpose of revenue, but to restrict the use of opium as far as may be accomplished by charging the maximum price that can be obtained, without promoting smuggling or contraband in any form. This policy has never been departed from. In support of the anti-opium contention, a single sentence of the evidence of the late Sir Cecil Beadon before the Finance Committee of the House of Commons, has been separated from the general and lengthened examination to which he was subjected. In this manner an entirely erroneous impression is given of his views and of the action of the Government in the restriction of the sale of opium in India. When asked to state whether the use of that drug was injurious to the character of the cultivators, Sir Cecil Beadon said that it was not injurious. He also said that they were as fine and healthy a population as in any part of India; that he had been a great deal among the poppy cultivators of Behar, and considered them a very healthy race, and never saw any of them suffering from the use of opium. He also said that, as far as his knowledge went, opium was not as injurious as alcoholic stimulants. Sir Frederic Halliday, the first Lieutenant-Governor of Bengal, before the same committee of the House of Commons, concurred in the statements of Sir Cecil Beadon on the fiscal and social relations of the opium sold by the Government.

Another confident statement of the counterblast is, if possible, more mischievously inaccurate. It is that "as a result of the facilities afforded by the Government for the opening of opium shops and for the free purchase of opium by all and sundry, the habits of opium smoking and opium eating are very rapidly growing among our Indian fellow subjects, and it need hardly be added that the effects of such indulgence are both moral and physical debasement. Neither can it be denied," continues this erroneous appeal, "that the free sale of opium opens the door in India, as in China, to innumerable acts of suicide, and, still worse, to the widespread inoculation of children with the opium habit from the practice of the mothers using it to narcotise their children while they are at work." Not a single authentic figure or fact in support of the accuracy of any part of this statement has been produced; and, if it can, is it possible to show that whatever increase there may be is in greater proportionate extension than the marvellous increase of the population shown by the late census? Opium smoking is not an Indian vice, and is comparatively little resorted to. That there has been an increase of opium eaters is probable. What proof is there, then, that any widespread moral and physical degradation has been the

result in British India of the opium habit? If such proofs exist, I am unacquainted with them, and have failed to discover them. I have in a former paper shown that among more than 300,000 prisoners in Bengal there was no record of crime due to opium, and no disease attributable directly to the same cause. There was an equal absence of insanity.

Among the Chinese residents in Calcutta, some 600 in number, I never in the many years I lived amongst them saw an emaciated opium drunkard, and the same is true of the up-country colony of Calcutta, now, and probably then more than 1700 in number. The opium agent of Gya, to whom I have referred above, in his twenty-one years' experience has never seen one, among the many thousands of cultivators who came under his personal observation.

And now as to the physiological effects of opium consumption in India. In the scientific investigation of the matter made by Mr. Vincent Richards at Balasore, in the Province of Orissa, which contains approximately a population of 5,720,000 souls, he estimated that 1 in every 12 or 14 of the population uses the drug, and that the habit is increasing. Of the 613 opium eaters examined by him, the average age of commencement of the habit was twenty to twenty-six years for men, and twenty-four to thirty for women. Of this number 142 had practised it from ten to twenty years, 62 from twenty to thirty years, and 38 for more than thirty years. The majority took opium twice daily, from two to forty-six grains, the larger doses the exception, the average being from five to seven grains daily. The dose when large had been increased from the beginning; when small there was no increase at all. The causes of increase were disease, example, and a belief in its aphrodisiac powers. The diseases were chiefly malarious fevers, dysentery, diarrhoea, hæmoptysis, rheumatism and elephantiasis. A number began the practice in the famine year 1866, as it enabled them to exist on less food and mitigated their sufferings. Others used it to enable them to undergo fatigue and to take long journeys. Dr. Richards concluded that the excessive use of opium by the agricultural classes, who were the chief consumers, is very rare indeed in Orissa. Its moderate use may be, and is, indulged in for years without producing any very decided or appreciable effect, except in weakening the reproductive powers, the average number of children of opium eaters being 1.11 after eleven years of married life. This (the opium habit) compares favourably as regards crime and insanity with intoxicating drinks. The inhabitants of Balasore are a particularly law-abiding race, and the insane form only 0.0069 per cent. of the population." Brigade-Surgeon Dymock of Bombay (Western India) concurred in the above view regarding the moderate use of opium, and believed that excessive indulgence was confined to a comparatively small number of the wealthy classes. Sir Wm. Moore, a most competent and reliable observer, had similar experience after long residence in Rajputana. Another of the best authorities on the subject was of opinion that the spread of the habit was in part due to the prohibition among Mahomedans of the use of alcohol, and to some extent to the long religious fasts of Buddhists, Hindus and Mahomedans, in which it is used to allay hunger and to prevent exhaustion. I myself have known Mahomedan patients in my wards, almost *in extremis*, to refuse to take any medicine in which they were told there was alcohol.

Early in the present year a meeting of the Calcutta Medical Society was held, at which the effects of the habitual use of opium on the human constitution were discussed. At this meeting Surgeon-Lieutenant-Colonel Crombie narrated visits which he, with other medical officers and three non-professional gentlemen, had made to several opium dens in that city. The places seen were orderly and well conducted, the chief of them being as quiet as a prayer meeting. The opium eaters were healthy, strong, intelligent men with one or two exceptions; and some of them had been opium eaters for years without showing any signs of degradation and debasement from it. Indeed, they were noted as an unusually bright, intelligent lot, with "broad frames, bravery muscles and healthy, pliant skins." So long as a man had sufficient food, the general impression of the opium eaters was that the opium eating did not do him any harm. The users of opium scouted the idea of opium consumption being as harmful as alcoholic excess. "Look at us," they said; "you find us here, after two or three hours of opium smoking, sitting and talking quietly; if we had been drinking we should have been quarrelling and fighting"; and the gentlemen who visited them agreed with this opinion. Surgeon-Lieutenant.

Colonel Crombie smoked an opium pipe, prepared *à la Chinoise*, and it had no effect upon him. In one opium shop only was any sign of unhealthiness seen. In this, which was patronised by a lower order of customers, the opium smoked was a watery extract called Mandat. Of the smokers, two looked decidedly ill, emaciated and cachectic. One of them had smoked Mandat for twenty, and the other for fourteen years. One only showed signs of intoxication, and he was a regular visitor and always went away muddled. One man, of about fifty-four years of age, healthy looking and robust, said he had smoked Mandat for thirty-five years without any harm.

I have not seen the text of the discussion referred to, but if this deeply interesting report contains, as I believe it does, a fair sample of the opium saloons of Calcutta, how can it be reconciled with the contention of the counterblast? Dr. W. J. Simpson accompanied the writer on the last visit to the Mandat shop, and both the visitors were surprised at the readiness and intelligence of the opium smokers, in discussing the question of the evils of the habit. The servant of the shop said he had smoked Mandat for fourteen years, but gave it up six months before, and took to opium eating with benefit.

If the Government of India could see its way to order a general inquiry into the assertion of the widespread evils alleged by the anti-opium agitators to exist at present, un-mixed good would be the result, in whatever direction the careful collection of the facts pointed. The late Surgeon-General Edward Balfour of Madras wrote that he had seen many smokers of the extract of opium, and that he had purposely sat among them on prolonged occasions in an opium saloon at Madras, and that he had also seen in India numerous children and grown-up people under the influence of opium without any resulting evil.

The most crucial example of all is, however, the province of Assam, which has been regarded as a reproach to the Government in the matter under consideration. When made over to us by the treaty of Yandabu in 1826, the lower grades of its diminished population, from the cruelty and oppression of its Burmese masters, were in a deplorable physical state, which may in some measure account for the general abuse of opium that then prevailed. To the ill-fed, ill-clothed, half-starved dwellers in conditions of malarious exhalations of the most deadly character, opium would be a source of comfort and consolation which no other means could supply. When, therefore, in due time, the cultivation of the poppy was interdicted, the order was not vigorously carried out from motives of mistaken humanity and from an ill-founded belief that the disuse of opium could not be effected without serious risk to life. A preparation called "Kaneec," obtained from an indigenous poppy grown in their gardens, was quietly allowed, and I will give the history of it in the words of the distinguished writer who has kindly given me the information, which is as follows. "When the poppy head has arrived at the proper maturity, incisions are made in it, and a narrow bandage of fine soft cotton-rag is wrapped round the head. When the rag has absorbed all the juice of which it is capable it is unwound, dried, and put by for use. This is kaneec, and I believe I may say, with hardly any exaggeration, that every true-born Assamese man, woman and child consumed it, cutting off bits of the rag when they felt a call, and chewing them as sailors do tobacco. The baby got it to suck with its mother's milk, and so it came about that every child was reared on kaneec and grew up a kaneec eater. After I took charge of the Assam Agency I waged a fierce war against this illicit kaneec cultivation, and then when, as a consequence, the demand for the Government opium (which had previously been slack) increased, I increased its price by 'leaps and bounds.' When I left Assam infants were no longer fed on opium, its use by women had much gone out of fashion, and the adult male population could no longer indulge in it *ad libitum*, and had to do honest work to procure the means of indulgence. I need not deny that there was a large increase of opium revenue, but it was an increase measured by the moral and physical improvement of the people."

This graphic and truthful picture places in a very different light the principles under which the Government act to the interpretation of them given in the Anti-opium Circular. Maharaja Narendra Krishna, with whom I was personally acquainted when in India, says that many elderly and old Hindus take opium, and that not a few young men wean themselves from drinking habits by betaking themselves to it. When taken by the camel drivers in the sandy

deserts of Western Rajputana it enables the men to subsist on scanty food and to bear without injury the excessive cold of the desert winter nights, and the scorching rays of the sun. Opium acts in Rajputana as a preventive of malarious fever. The late eminent surgeon, Sir Benjamin Brodie, was of opinion "that the effect of opium when taken into the stomach was not to stimulate, but to soothe the nervous system. It might be otherwise in some instances, but these were rare exceptions to the general rule. The opium eater," he added, "was in a passive state, satisfied with his own dreamy condition while under the influence of the drug. He was useless, but not mischievous. It was quite otherwise with alcoholic liquors." Has an opium eater ever been found to have knocked out his wife's brains? Is that civilised proceeding altogether unknown to the alcoholic drunkard at home?

I cannot better conclude this brief *résumé* of the most reliable views upon the moderate use of opium than with the impartial summing up of one of the best authorities on the question. "So far as can be gathered from the conflicting statements published on the subject, opium smoking may be regarded much in the same light as the use of alcoholic stimulants. To the great majority of smokers who use it moderately it appears to act as a stimulant and to enable them to undergo great fatigue, and to go for a considerable time with little or no food. According to the reports given by authorities on the subject, when the smoker has plenty of work it appears to be no more injurious than smoking tobacco. When carried to excess it becomes an inveterate habit, but this happens chiefly in individuals of weak will power, who would just as easily become the victims of intoxicating drinks and who are practically moral imbeciles, often addicted also to other forms of depravity. The effect in bad cases is to cause loss of appetite, a leaden pallor of the skin and a degree of leanness so excessive as to make its victims appear like living skeletons. All inclination for exertion becomes gradually lost, business is neglected and certain ruin to the smoker results." How is it with the same class of alcoholic drunkards?

(To be concluded.)

## TUBAL MOLES AND TUBAL ABORTIONS.<sup>1</sup>

By J. BLAND SUTTON, F.R.C.S. ENG.,

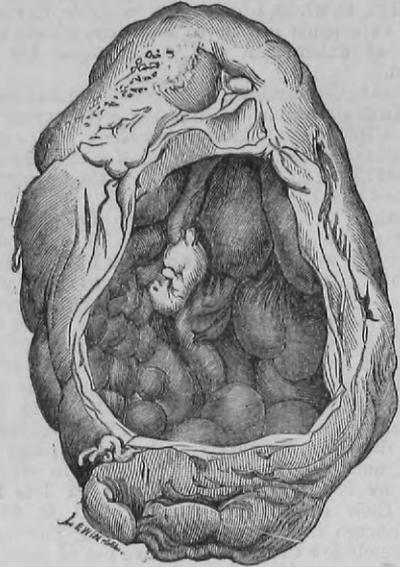

ASSISTANT SURGEON, MIDDLESEX HOSPITAL.

In a paper read before the Royal Medical and Chirurgical Society<sup>2</sup> I drew attention to the fact that the ovum in a case of tubal pregnancy is liable, like the ovum in uterine pregnancy, to become converted into a mole (apoplectic ovum). Since that date my observation has been abundantly confirmed in Germany, America and England; indeed, the condition is now so well recognised that it seems almost superfluous for me to again direct attention to it. However, I feel it necessary to do so on account of the many opportunities I have enjoyed of studying the tubal mole since the original paper was published; also it is necessary to correct a few misconceptions.

Tubal moles differ from uterine moles in several particulars—indeed the points of distinction are such as to enable us readily to tell one from the other. The uterine mole is more or less spherical; the amniotic cavity is of fair size and occupies the centre of the mole. The embryo may, or may not, be present. Sometimes it is represented merely by an ill-shaped mass pendulous at the end of the cord. Even when the embryo can be recognised it is very misshapen and the umbilical cord is often œdematous. (Fig. 1.) A tubal mole in its early stage is spherical, but, after attaining the dimensions of a walnut, becomes ovoid. (Fig. 2.) In the majority of cases the amniotic cavity occupies an excentric position; in consequence of this peculiarity the thin amnion is easily ruptured and permits the escape of the embryo. This explains the difficulty of finding the embryo in many cases where the mole has been discharged through a rent in the wall of the tube or aborted through an unclosed ostium, accompanied, as the rule is in these cases, with free hæmorrhage. The mole is easily found in the clot, but if the embryo has escaped from the amniotic cavity the chances are that it will not be

recognised. It must not be imagined that because the embryo has not been found it has been dissolved by the peritoneum. On one occasion I collected all the blood and clot which I removed during an operation five weeks after the rupture of a gravid tube and disintegrated it by a gentle stream of water. In the course of this manœuvre the embryo came to the surface, was promptly recognised and caught. As is the case with uterine moles, the embryo sometimes dies

FIG. 1.

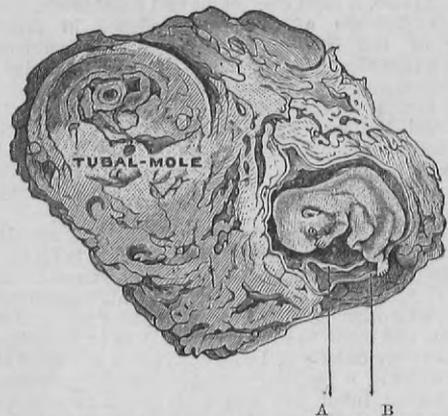

A Uterine Mole.

very early, and the amniotic sac contains nothing but a small quantity of fluid. When the mole on its escape from the tube is discharged between the layers of the broad ligament it becomes so compressed that the embryo is found flattened out like a succulent flower firmly squeezed between the leaves of a heavy book.

It will be necessary to offer a few remarks on the recognition of a tubal mole. When a mole is found with an embryo

FIG. 2.

in the amniotic cavity there cannot be any room for dispute. The same holds good for moles with an amniotic cavity, though no embryo is present. In hard firm clots in which the amniotic cavity is not recognisable, sections from the supposed mole must be prepared and examined with a microscope for chorionic villi. The presence of chorionic villi are as indicative of a mole as of the presence of an embryo. These villi are such characteristic structures that they cannot be confounded with "half-organised blood," as some writers

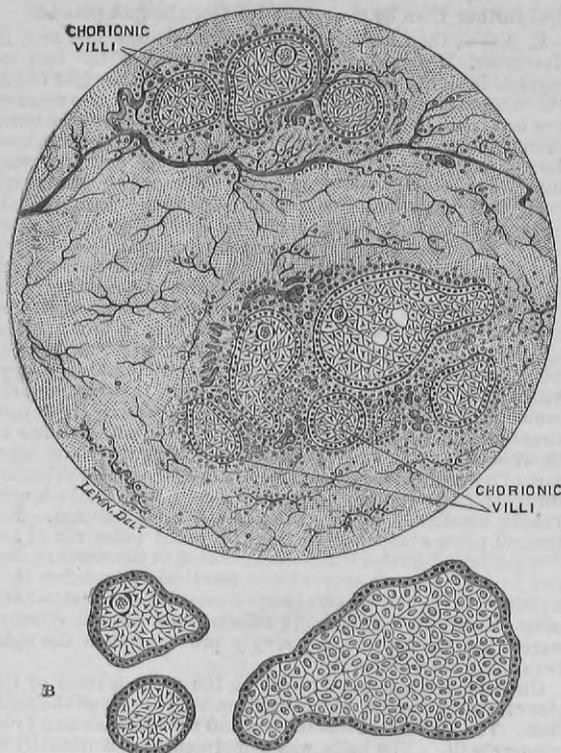

<sup>1</sup> Abstract of a paper read before the Medical Society of London, Nov. 7th, 1892. <sup>2</sup> Nov. 12th, 1889.

have suggested. The use of such an expression implies ignorance of even the elementary facts of histology. When seen in stained sections among bloodclot the villi are very striking objects, and in order to facilitate their recognition Fig. 3 has been prepared. They usually appear in sections as clusters of circular bodies; ten or more in fortunate sections may be counted together. More frequently they occur in groups of three or four and often a wide section of clot will be examined without finding more than two or three. Under a low power they present an external layer of epithelial-like cells, the central space being occupied by cells of irregular shapes. When examined under a high power the limiting layer is seen to be formed of a perfectly regular row of cubical epithelium; sometimes two rows of epithelium are present.

It is of great importance to appreciate clearly the characters of a tubal mole, for the presence of a mole is decisive proof of pregnancy. It must not be supposed that every bloodclot found in a Fallopian tube is a mole. That blood and bloodclots are occasionally found in the Fallopian tube unconnected with pregnancy is beyond all dispute. Anyone who has

remains open the ovum is in constant jeopardy of being extruded through it into the peritoneal cavity, especially when the ovum lies near or in the ampulla of the tube. When an impregnated ovum is thus extruded from the tube into the general peritoneal cavity it is invariably in the condition of a mole, and the accident is always accompanied by hæmorrhage. The extrusion of a mole in this way is indicated by the term "tubal abortion." Free hæmorrhage may occur from a gravid tube and the mole be still retained in consequence of its attachment to the wall of the tube. Under such conditions the bleeding may be repeated; this is known as "incomplete tubal abortion." Some of the most striking instances of recurrent hæmorrhages from gravid tubes occur when the ovum is too large to pass through the ostium. There is a variety of dilated tube which resembles a wine jar (amphora) without handles, and the ovum, though free to move about within the dilated portion of the tube, is as safely imprisoned as the wooden pea in a schoolboy's whistle.

FIG. 3.

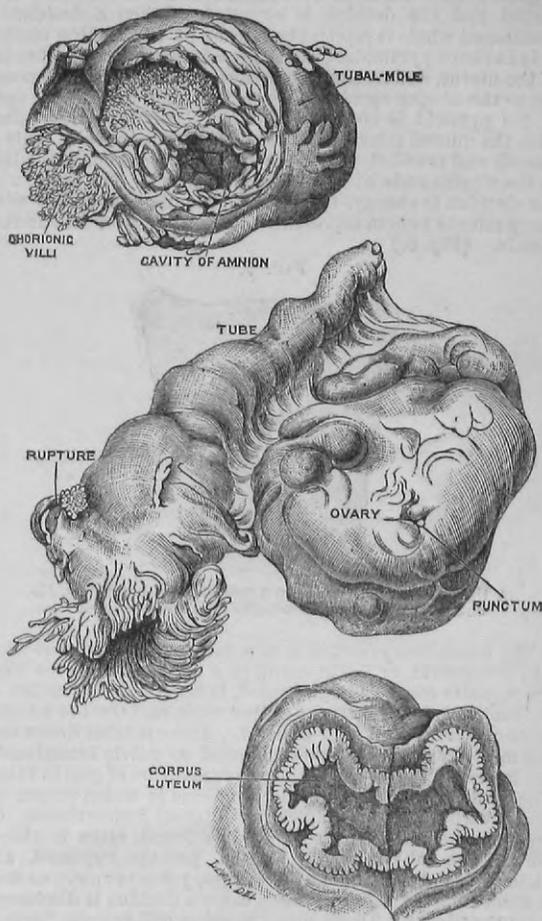

Chorionic Villi from a tubal mole (magnified) embedded in blood clot. A, Villi highly magnified.

taken even the smallest interest in the history of any branch of medicine must be aware that originally many conditions which we now know to be distinct were formerly grouped together under a comprehensive term. It was customary to apply the term "hæmato-salpinx" to accumulations of blood in the Fallopian tube independently of their origin. The discovery of the tubal mole has furnished a criterion for the differentiation of gravid tubes. Formerly the majority of Fallopian tubes containing bloodclot were classed as examples of hæmato-salpinx, and an examination of museum specimens demonstrates this absolutely. For the sake of accuracy in the future it will be necessary to reserve the term "hæmato-salpinx" for a non-gravid Fallopian tube distended with blood secondary to occlusion of the abdominal ostium.

The consideration of the occlusion of the abdominal ostium of the tube brings me to the question of tubal abortion. The retention of an impregnated ovum in the Fallopian tube leads to occlusion of the abdominal ostium, an event usually complete by the sixth but often delayed to the eighth week following impregnation. It is therefore a comparatively slow process. (When the ovum is lodged in the ampulla of the tube the ostium cannot close.) So long as the tubal ostium

FIG. 4.

A Fallopian Tube in which rupture occurred. The ovum escaped through the unclosed ostium, and at the time of the operation was lying among the fimbriae of the tube.

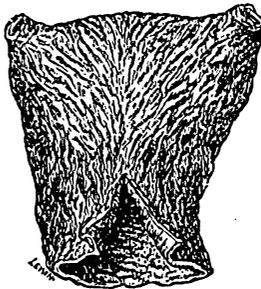

In some of these specimens the mole remains united by a portion of its circumference to the tubal mucous membrane.

A gravid tube may burst and the mole escape into the peritoneal cavity through the unclosed ostium. A specimen demonstrating this is represented in Fig. 4. I removed the parts from a woman twenty-nine years of age by abdominal section. At the time of the operation the mole was lying among the fringes of the tube and the ostium was widely dilated. On examining the tube a small rent was found in its walls capable of admitting the point of a pencil. At the time of the operation the mole was lying among the fimbriae of the tube and the ostium was widely dilated. The specimen is of value because it demonstrates that because an adventitious opening is found in the wall of a gravid tube, it by no means follows that the ovum escaped through it. (Fig. 4.) I was of opinion that the term "tubal abortion"

was introduced into literature by Keller; but this was an error, for G. Veit, in an interesting paper entitled "Behandlung der Extrauterine Schwangerschaft,"<sup>3</sup> distinctly refers to the extrusion of an impregnated ovum through the abdominal ostium without rupture of the tube, accompanied by hæmorrhage, under the term of "tubal abortion," and illustrates the condition by a sketch of a specimen. Like all who have observed this condition, he points out that the accident is a grave one for the patient. My own experience is that the hæmorrhage is more abundant in cases of tubal abortion than from rupture of the tube.

It will, perhaps, be useful to offer a few remarks on the decidua. When a Fallopian tube becomes gravid a decidua forms in the uterus, and this curious structure has a diagnostic value. This decidua is rarely retained until the completion of gestation and thrown off during the false labour. Usually it is discharged during the early period of pregnancy in small fragments, without producing pain, or else it is expelled *en masse* with symptoms of miscarriage. When a gravid tube ruptures or aborts, the uterus becomes disturbed and the decidua is expelled. When a decidua is discharged whole it represents a cast of the uterine cavity. It is in shape pyramidal; the base corresponds to the fundus of the uterus, and at each angle there is an orifice corresponding to the uterine opening of each Fallopian tube. The apex of the pyramid is occupied by a circular hole corresponding with the dilated internal orifice of the cervical canal. This is smooth and rounded, whilst the smaller orifices corresponding to the uterine ends of the tubes are ragged. The exterior of the decidua is shaggy, the interior smooth and dotted with many minute puncta representing the orifices of the uterine glands. (Fig. 5.)

FIG. 5.

A Uterine Decidua formed in a case of tubal pregnancy, discharged at the end of the eighteenth week of gestation.

The unnecessary formation of a decidua in the uterus when a tube is gravid, or in the cornu of a bicornuate uterus when the opposite cornu is impregnated, is a curious illustration of the traditional way Nature does her work, and teaches a lesson some of us may well take to heart. There is little doubt that the majority of cases formerly classed as pelvic hæmatoceles are in reality the result of rupture or abortion of gravid tubes. The cases in which doubts arise are those in which women are seized with symptoms indicating internal hæmorrhage. On opening the abdomen free blood is found, often in abundance. The tube is widely dilated, perhaps ruptured, and clots of blood hang about the fringes, yet no embryo or mole is detected. In some of these cases a decidua is discharged from the uterus. These doubtful cases will become fewer as operators become familiar with the tubal mole. The mole is so different from ordinary clot that there should be little difficulty in distinguishing it, except in cases in which it is very small.

The following is a summary of the views contained in this paper:—(1) The transformation of a tubal ovum into a mole or apoplectic ovum is beyond doubt; (2) the majority of specimens described as examples of hæmato-salpinx are gravid tubes; (3) rupture of a gravid tube and tubal abortion are the common causes of pelvic hæmatocele; (4) mesometric rupture of a gravid tube is a common cause of pelvic hæmatoma; (5) to affirm that bands of fibrin resemble chorionic villi indicates great want of histological knowledge; (6) every clot of blood found in a Fallopian tube is not a tubal mole.

Since the discovery of the tubal mole specimens of non-gravid Fallopian tubes are found to be so infrequent that in the last report of the museum of the Royal College of

Surgeons I notice an account of "an unequivocal example of hæmato-salpinx." This is a fair indication of the revolution which has taken place in our knowledge of the early stages of tubal pregnancy.

Queen Anne-street, W.

## A CASE OF

## LOCALISED GANGRENE OF THE LEG OCCURRING IN THE COURSE OF SCLERODERMA; AMPUTATION THROUGH THIGH; RECOVERY.

BY ALEX. G. R. FOULERTON, M.R.C.S., L.R.C.P. LOND.

THE following is the record of a somewhat unusual episode in the history of a case of general or diffused scleroderma which occurred in my practice at St. Bartholomew's Hospital at Chatham. With the clinical details of the case previously to the supervention of gangrene I do not now propose to deal further than by giving the briefest abstract possible.

E. A—, then aged twenty-two months, was first seen in November, 1888. About a month afterwards the first recognisable signs of scleroderma appeared in the right thigh. The whole surface of the body subsequently became more or less involved in the disease, which at last presented the usual characters of the fully developed stage of diffused scleroderma in children. I may here refer to the accompanying engravings, which were taken from photographs. They show fairly well an earlier and a later stage of the disease. Fig. 1, from a photograph taken in April, 1889, shows the right lower limb considerably enlarged; certain pigmentary changes are not, however, apparent. When the photograph of Fig. 2 was taken (April, 1890) the stage of gradual shrinking of the tissues had set in. In June, 1891, the condition of the right lower limb was as follows. The hip, knee, ankle and phalangeal joints were all strongly flexed and immovably fixed. The skin of the limb was everywhere tightly bound down to the underlying tissues; nowhere could it be pinched up or shifted laterally over the deeper structures. It was mottled here and there with patches of brownish pigment, and between these it was for the most part of a dead-white colour. The whole limb was considerably shrunken and very hard, feeling as cold wax to the touch. Tactile sensibility was apparently but little affected. The femoral pulse could be just felt, the pedal pulse not at all. The joints of the other limbs were affected in like manner, but in a less degree. It may also be mentioned in passing that whilst the skin and subcutaneous tissue and the joints of the other limbs were unilaterally affected the several changes were from the first more strongly pronounced in the right lower limb than elsewhere.

On July 1st I found that during the night a bulla of the size of a crown piece had formed on the dorsum of the right foot. The whole foot was tender, and the child seemed to be extremely ill. The bulla was punctured and a quantity of blood-stained serum escaped. The foot was washed with a weak solution of iodine, the bulla was sprinkled over with iodoform, and the leg was then enveloped in absorbent wool. Next morning it was found that an exactly similar bulla had formed over the internal condyle of the right femur. This was dealt with in the same way as before. The child's condition was worse, and stimulants were given freely. On July 4th she began to improve. Moist black sloughs occupied the sites of the two bullæ. The child's condition remained fairly satisfactory until July 18th, during which time the sloughs were kept practically odorless by due attention to cleanliness, but were not otherwise interfered with. On July 19th things changed for the worse again. The temperature, hitherto normal, rose to 100° F. in the evening. The pulse was very small and irritable. The child herself was restless and seemed in pain, moaning continually. On July 21st she was all but exhausted, and the case seemed to be well nigh hopeless. In the evening the two sloughs separated, leaving the tarsal bones and the inner aspect of the lower end of the femur quite bare, clean and white. The skin of the leg elsewhere was in exactly the same condition as it had been before the supervention of the gangrene, which had never evinced the slightest tendency to spread. There was a noticeable absence of any signs of inflammation in the neighbourhood whence the sloughs had

<sup>3</sup> Verhandlung der Deutsch Gesch. für Gyn., 1890, S. 171.

separated. The child had hitherto been treated as an out-patient, as the parents were very averse to her removal into hospital. However, I still felt justified in urging them to give her the last chance that an operation might afford, poor though that chance seemed to be. She was accordingly admitted on July 22nd, and I amputated the limb on the following morning. In amputating a circular incision down to the bone was made in the middle third of the thigh, the skin and muscles being divided at the same level. From the circular incision a longitudinal one was carried up on either side of the thigh. The anterior and posterior flaps thus formed were then raised from the femur by means of a director. These flaps were so rigid and hard that some difficulty was experienced in dividing the bone sufficiently high up; and it was only after somewhat forcible retraction of the flaps and tissues above them that the femur could be divided with bone forceps at the required level. The femoral and profunda arteries were then tied and an elastic tourniquet which had been lightly applied was removed. Both the vessels tied were of extremely small calibre and no other bleeding points were seen. The stump was then washed with weak iodine solution and some boracic acid powder was dusted over the raw surface. A narrow slip of gutta-percha tissue was placed in either angle of the wound to provide for

and better than she had been at any time during the previous two years. The tissues of the remaining portion of the right thigh were much softer than they had been before the operation. Portions of the skin elsewhere showed a similar improvement. In short, the scleroderma appeared to be undergoing involution. I saw the child again in December, 1891, and in January and February of the present year, and the improvement appeared to be sustained. After February I did not see her again until June, and was much disappointed to find that the improvement had been but temporary and that the disease was now progressive. Whether the operation, by producing some alteration in the general nutrition, or the treatment in hospital was responsible for this temporary improvement—or whether, on the other hand, it was purely accidental—I am quite unable to say. When last seen the stump surface was all that could be desired; but, owing to the extreme flexion of the hip-joint, the stump itself was drawn up against the abdomen.

In conclusion, one or two general points may be referred to. First, the occurrence of gangrene must be noted as a most uncommon complication of a disease itself sufficiently rare to be of interest on that account alone. Then, again, I regard the result of the amputation, through tissues but ill adapted to such a procedure, as having been extremely

FIG. 1.

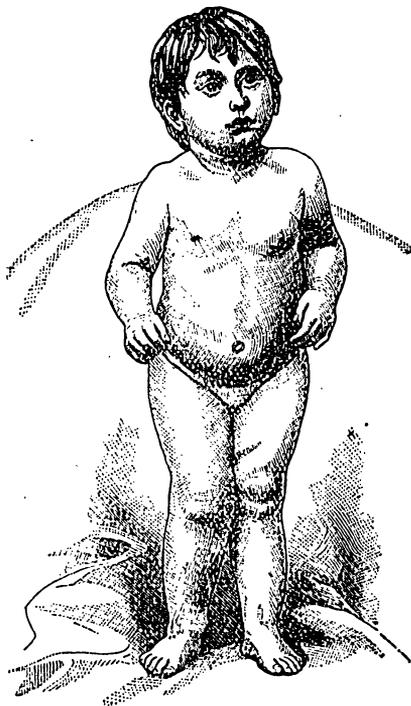

FIG. 2.

Drainage, the flaps were brought together by deep and superficial sutures, and the stump dressed with absorbent wool. The result of the operation was altogether satisfactory. The child's condition was markedly improved within an hour or two of the operation and her progress was continuous. The amputation was performed on July 23rd and for the next few days the temperature rose to about 100° F. in the evening, falling to the normal in the morning. On July 27th the stump was dressed for the first time. There was very little discharge, but the extreme edge of the anterior flap was just blackened for about a quarter of an inch. The drainage slips of gutta-percha tissue were removed and the stump was dressed as before. The next dressing was on July 30th, when two of the four deep sutures were removed. The stump was then dressed for the third time on Aug. 2nd and all the remaining sutures were removed. The small shred of blackened skin had separated, the flaps had firmly united, and the line of union had almost healed up. A day or two later I left Chatham and did not see the child again until Sept. 21st. She had then been discharged from the hospital for some time and a considerable improvement in her general condition was noted. She looked stronger

fortunate. A third point of interest is the condition of the parts removed. The cross section of the portion of the limb amputated on July 23rd showed that all the tissues of the part were affected. The skin was intimately connected with the subcutaneous tissue, which was very hard and considerably increased in thickness. The subcutaneous tissue could not be peeled off the fascia of the muscles without tearing away the surface of the degenerated muscle substance in places. The muscles had undergone complete degeneration and were of a greyish waxy appearance. The point which perhaps struck me most was the almost bloodless condition of the limb. As remarked previously, after the femoral and profunda arteries had been tied there was not a trace of oozing from the raw surface. The bones were much atrophied. I am unable to give any further details as to the morbid anatomy. The limb was put on one side for further examination in a preserving fluid, which unfortunately proved inadequate for its purpose, and consequently when the jar containing it was opened a week or two later the specimen was found to be in an advanced stage of decomposition, so that further examination was impossible. It is not proposed to discuss the pathology of scleroderma at any length

here. I would only suggest that to classify it with skin diseases, as is commonly done, is to take a somewhat narrow view of the subject. I must say that it seems to me to be highly probable that the localised form of scleroderma sometimes met with in adults is pathologically a different disease from the diffused scleroderma usually met with in young children. Clinically, at any rate, the difference is considerable. In the case under consideration the changes in arteries, muscle substance and bone are quite sufficiently explained by regarding them as secondary degenerations due to disuse. I would go a step further, and suggest that the skin changes may also be ranked as secondary. I would then regard scleroderma rather as a disease primarily affecting a widely spread and genetically allied group of tissues of mesoblastic origin, and including the subcutaneous areolar tissue, the fascia of muscles and the fibrous capsule of joints. This being assumed, the fixation of the joints with disuse of the limbs would be followed by atrophy of muscle and bone, and diminished vascular supply would result in the loss of function, and in its turn accentuate the degenerative changes already in progress. These degenerative changes with impaired vascularity culminated in gangrene in the case just related. Pigmentary and other changes in the skin may also be due to altered conditions of nutrition in the skin overlying a portion of the subcutaneous tissue already affected by the disease. To support, however, my contention as to the original site of the disease processes much more would have to be advanced than has been done here. This I shall endeavour to do in a future paper.

Brompton-road, S.W.

## WHY DO STRICTURES OF THE URETHRA RELAPSE ?

By C. MANSELL MOULLIN, F.R.C.S. ENG., M.D. OXON., &c.,  
SURGEON TO THE LONDON HOSPITAL.

IT is notorious that in the vast majority of cases strictures of the urethra, if left to themselves after dilatation or division, recontract and in a little while become as narrow as they were before. It is not, perhaps, so well known that this is not an invariable rule. I have published several instances in which permanent recovery, proved by the duration of many years, followed external urethrotomy, and I have shown that the same result may occur after prolonged perineal drainage, while it is not uncommon to meet with cases in which, after internal urethrotomy, catheterism has been practised, at first diligently, then more or less carelessly, and at length has been neglected altogether for many years without there having been any perceptible degree of return. It seems, therefore, of some interest to consider what such cases have in common, and why methods of treatment apparently the most diverse succeed sometimes, when usually they are followed by so different a result. At first sight the particular kind of stricture does not appear to have anything to do with it. Those that were treated by external urethrotomy were of the severest type, dense and hard, with an enormous amount of peri-urethral infiltration; the others for the most part could not be felt from the outside, and had been noticed only recently, although from the history it was probable some contraction had been there for a much longer period. All of them, however, presented certain features in common. The stricture was in every case deep down in the urethra; it had followed gonorrhoea, sometimes one attack, more frequently several. There had been in all a long period of gleet discharge, and no patient had noticed any alteration in the size of the stream until some considerable time had elapsed. Strictures that agree in these respects may be urethral or peri-urethral—that is merely a question of time; the important feature is that in none of them is there any actual loss of substance; the mucous membrane lining the urethra has not been destroyed at any one spot; the constriction is not due to the contraction of a scar, but to the organisation and condensation of the inflammatory exudation that is poured out in and around the walls of the canal. This distinction is not taken into sufficient account in the system of classification ordinarily adopted for organic strictures of the urethra. They are described in terms expressive of their shape, the appearance they present in the bodies of those who have died from the complications they cause, the special symptoms that accompany them, or some other and often

entirely accidental circumstance in connexion with them; but their mode of origin, whether they have followed a syphilitic sore or extravasation of urine, or an attack of chronic inflammation, and the immediate cause of their formation, whether they have been preceded by ulceration and destruction of the mucous surface or not, are not connoted in any way. Yet this is the main distinction which marks them off at once into two great classes, one in which the whole thickness of the lining membrane of the urethra has been destroyed at some one spot, and the other in which it has not. In the ordinary form of gonorrhoeal stricture it has not; the contraction commences as an inflammatory effusion in the substance of the mucous and submucous layers, very often at the base of a little button of granulation. Unless the attack has been very severe, attended with hæmorrhage, or treated with unnecessary vigour, the lining membrane, although it may be condensed and hardened, is not destroyed; it can nearly always be dissected off, thinned it is true and discoloured, with its surface altered in texture and appearance, but still intact. There is no cicatrix in the ordinary sense of the term. On the other hand, syphilitic sores, nearly always leave a contracting scar, usually near the orifice; so does extravasation of urine, unless the opening in the urethra is a mere pinhole, and so may gonorrhoea if the mucous membrane is destroyed at any one spot by ulceration or torn by the passage of catheters or in the barbarous attempt at breaking down chordee. Cicatricial strictures of this kind are distinguished by the rapidity with which they form and the speed with which they recontract. I have known them well marked within a few weeks of the attack that originated them, and there can be little doubt that for them at least, no matter what treatment is adopted, regular catheterism at frequent intervals is always necessary.

With the others, those in which there has been no breach of surface of any size, the case is different, and close observation of a considerable number has convinced me that a certain proportion can be cured permanently by adopting suitable methods and maintaining the treatment for a sufficient length of time. The cause of their contracting originally is different. It is not now the presence of a scar due to a loss of surface, which nothing but transplantation can replace; it is merely the slight persistent irritation kept up by the passage of the urine over a tender part of the urethra. At first the progress of the stricture is exceedingly slow, the irritation is very slight, and the amount of lymph effused very small, scarcely making a perceptible difference in the calibre of the urethra even at the end of months; but as years pass by this fractional amount accumulates and grows harder, the obstruction becomes more marked, the straining and irritation that it causes more severe, and the amount that is poured out larger and larger until at length it forms a dense mass, filling the interstices not only of the mucous and submucous layers, but those of the corpus spongiosum and bulb as well, growing harder and more rigid with ever-increasing rapidity the longer it lasts; and it is for the same reason, and not because there is a scar, that these strictures relapse so often after treatment. The whole of the obstruction is not dispersed; some, ever so little it may be, is left, and sooner or later the same old vicious circle begins again, the obstruction causing irritation and the irritation making the obstruction worse. Unless the whole is removed and the lining membrane of the urethra restored to its natural flexibility there can be no permanent cure. How this is to be accomplished varies naturally with the kind of stricture; but whatever the treatment adopted, whether it is division or dilatation, it must always be borne in mind that this is only a preliminary. Dilatation may stretch and urethrotomy may divide the rigid lymph, but neither really does away with the obstruction. It is diminished so that there is no straining and much less irritation during micturition, but that is all. The stricture tissue is still there; complete removal can only be effected by the very slow process of fatty degeneration and absorption, and for this it is absolutely necessary that there should be a long period of perfect rest and freedom from all spasm and irritation. How far this can be secured by dilatation alone is very doubtful. It may succeed if the stricture is very recent and still confined to the walls of the urethra, but if there is already a large amount of peri-urethral infiltration it is almost useless, except as a temporary measure; and if the stricture is old and hard, whether it is confined to the mucous and submucous coats or not, it is scarcely any better, even though it is carried to the point of extreme distension. The lymph is

stretched, a great deal of it disappears and the muscular fibres that surround the urethra are paralysed for a time; but in a very little while after the catheter is withdrawn the contraction begins again. The tenderness and irritability are still there; the tone of the muscular fibre returns and as soon as the stream of urine begins to unfold and open out the walls of the canal the stimulus sets up a slight but sufficient degree of contraction. So long as the stricture is wide the obstruction this causes is scarcely perceptible: the hyperemia passes off almost at once, and there is so little exudation that the occasional passage of a catheter is sufficient to keep the channel dilated; but if the case is neglected, little by little the lymph collects until at length, when the contraction has passed a certain point, further progress is by leaps and bounds. For a long time I have practised internal urethrotomy after thorough dilatation, with the view of preventing muscular spasm and giving a long period of perfect rest for the removal of the last of the exudation; and although it is difficult to prove, I feel convinced that this method has met with a higher degree of success than either dilatation or internal urethrotomy by itself. Internal urethrotomy without previous dilatation succeeds sometimes, just as simple dilatation does in recent cases in which the stricture tissue is confined to the walls of the urethra, but not in those in which the exudation is old and hard, or very widely spread; absorption is too slow. The muscular fibres are divided so that there is no spasmodic contraction; but division, however thorough it is, does not restore the parts to their natural state. The expansion of the urethra when the urine passes down it is not smooth or even until the whole of the exudation has been absorbed; and this takes too long. Before the old and hardened lymph has had time to disappear completely the obstruction and irritation that it causes have led to a fresh deposit and the narrowing has commenced again. Unless the stricture is a recent one, and the exudation comparatively soft, dilatation is always necessary after internal urethrotomy—at any rate, for a time. Occasionally, if it is kept up diligently for some months and gradually left off, no recontraction takes place. External urethrotomy, on the other hand, practically fulfils all the required conditions, and to this it owes its success in some of the very worst cases. The whole of the urine escapes without tension or straining; muscular spasm is out of the question; however hard or widely spread the exudation, the whole of it must soften and melt away before the wound will close, and meanwhile the channel regains its natural size and the walls their flexibility. The rest that it gives is perfect, and certainly in some instances absorption is complete and the cure permanent, a fact that deserves more attention than it has hitherto received, for this method of treatment is rarely given an opportunity except in cases in which every other measure, including dilatation and internal urethrotomy, has been tried and has failed time after time.

Wimpole-street, W.

## TWO CASES OF DERMATITIS GANGRENOZA INFANTUM.

By CAMPBELL WILLIAMS, F.R.C.S. ENG. &c.

DERMATITIS GANGRENOZA INFANTUM (Crocker) was first described by Mr. Hutchinson under the name of "varicella gangrenosa." As it is one of the rarer diseases of childhood I venture to record the two following cases. They are to an extent interesting in that in neither case could one obtain history or evidence of vaccinia or varicella as an etiological factor. Nor were they, as far as could be seen, the subjects of rickets or congenital syphilis. In the case that recovered the child was unvaccinated, and had not suffered from chicken-pox or other febrile disorder. It was badly nourished. Five preceding children had died in infancy from "consumption of the bowels." As is well known, this vague term often means diarrhoea from improper feeding. The second case had likewise escaped the usual preceding ailments, but was the subject of miliary tuberculosis. Dr. Thomas Barlow first pointed out the frequent presence of tubercle in this disorder. In 1888 I made a necropsy upon a child that had died from gangrenous dermatitis, when Dr. Barlow drew my attention to the combination, which was also present in that case. From a pathological standpoint these cases may

be regarded as due to microbic infection. In a way they are analogous to acute necrosis if skin is substituted for bone.

CASE 1.—C. W—, aged two years, male. This child was admitted into University College Hospital under the care of Mr. Christopher Heath on Sept. 9th. Being in charge of the skin department in the absence of Dr. Radcliffe Crocker, I was asked to see the case. The child was the younger of two. The elder had died from a tumour in the abdomen, the nature of which could not be elicited. The mother had also had two miscarriages. No signs, present or past, of infectious disorders were obtainable. The mother asserted that the child never had chicken-pox and that he was vaccinated in the early months of life. He did not snuffle, nor was there any discoverable evidence pointing to congenital syphilis or rickets. The eruption was first noticed on Sept. 7th—i. e., two days before admission. It was described as having begun as pimples about the size of pinheads. These became vesicles and later became covered by black scabs. The patient had diarrhoea for fourteen days prior to Sept. 9th, and had vomited slightly during that period. On admission the child seemed moribund. There were signs of broncho-pneumonia at the left apex. The pulse was small and rapid, 120, whilst the temperature was 99° F. During the night it rose to 102°. This fell next day to 101°, at which point it remained until just before the child's death. This occurred twenty-seven hours after admission. During this time he had twelve stools, which were very offensive, but brown in colour. There were altogether twelve ulcers upon the child's body. There was one upon the scalp in the region of the lambdoid suture. Here the scab had not separated and was suggestive of varicellous origin of the disease; but there were no other traces about the head or face to support that theory. In the remaining lesions the slough had separated, leaving typical ulcers. They were roundish, sharp-edged and conical. The sides and bases were covered with a thin adherent brownish-black slough. An inflammatory areola of about one-twelfth of an inch in width was visible around each lesion. The ulcers varied in depth from three-quarters to a quarter of an inch. There was one upon the left buttock, about the size of a shilling; it extended down to the deep fascia. A group of four occupied the posterior aspect of the right thigh, another group of four upon the right calf and two small ones upon the flexor surface of the left thigh. The left calf was clear. None of the ulcers in these groups had coalesced. The skin between them was apparently healthy. The child was fed on milk and brandy. The ulcers were dusted with iodoform crystals and dressed with iodo-vaseline.

The post-mortem examination disclosed the presence of miliary tuberculosis. Both lungs were studded with tubercles, whilst the apex of the left was quite pneumonic. The apical portion of the left parietal pleura was adherent to the visceral, and there was a patch of tubercle upon it. Two bronchial glands had cascated. The liver, spleen and kidneys, together with the mesenteric glands, were all affected. The brain was not examined.

CASE 2.—J. N—, aged seven months, a poorly nourished male infant. A brother, aged nine years, was alive and healthy. The next five children had all died in infancy, marasmic. This boy, the youngest born, was said to have been strong at birth. For the last few months the infant had been put out to nurse during the day whilst the mother was at work. On Aug. 30th I first saw the child. He did not seem seriously ill. The temperature was 99·8° F. The child had not been vaccinated and was said not to have had chicken-pox or other exanthem. There were certainly no recent signs of congenital syphilis. The disease was stated to have started a week previously as pimples. These the mother ascribed to bug bites. The papules were noticed to rapidly enlarge and become covered with black scabs. When seen by me the child had an ulcer on the right buttock from which the scab had separated, leaving a circular, depressed ulcer of half an inch in diameter and about as much in depth. The wall was covered by black-brown slough. There was a similar one on the right flank and a third one upon the abdomen. Here ulceration was going on beneath a black crust. Lastly, there was one upon the upper lip; it was quite superficial, but there was destruction of tissue such as one does not observe in impetigo contagiosa. A gland in the right inguinal region suppurated and was opened on Sept. 2nd, and did well. The child was properly fed and given small doses of cod-liver oil. As the bowels were irregular minute doses of mercury with chalk were given every other night. The ulcers were first dressed with dilute ammoniated mercurial ointment. As they did

not show signs of improvement iodoform crystals and iodo-vaseline were substituted. They at once commenced to heal by granulation, and by Sept. 27th they were all cicatrised. My friend, Dr. W. Carr, kindly saw the case with me and concurred in the diagnosis.

The above cases go to confirm the view held that the sphaclodermatous condition is not necessarily secondary to varicella or vaccinia. I believe Mr. Hutchinson acknowledges this. That tuberculosis takes a very prominent position amongst the predisposing causes, the frequent localisation of the disease to the buttocks and thighs, where the skin is inflamed or sore from wet diapers &c., suggests that the process is primarily one of inoculation. The rarity of the disease and the frequency of all the predisposing causes seem in favour of a specific micro-organism as the direct excitant.

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

#### METROPOLITAN HOSPITAL.

ULCERATIVE ENDOCARDITIS; CEREBRAL HÆMORRHAGE;  
DEATH.

(Under the care of Dr. HOWARD H. TOOTH.)

THE difficulty which may be met with in making a correct diagnosis in some of the milder cases of ulcerative endocarditis is well illustrated by the account of this case. It is also interesting to the profession from the fact that the cause of death was cerebral hæmorrhage, this mode of termination being unusual. Our readers will recollect that Dr. Osler in his Gulstonian Lectures, which we published in THE LANCET,<sup>1</sup> divides the disease into three groups—the pyæmic, the cardiac and the cerebral; the third of these does not, however, refer to cases in which hæmorrhage into the brain is met with, but to those in which a meningitis has developed, often of a suppurative character. For the notes of this case we are indebted to Mr. C. P. Handson, house physician.

G. H—, aged twenty-two, was admitted into the Metropolitan Hospital on Sept. 15th, 1892. He was a painter by trade. In September, 1891, the patient felt pain in the left side of the abdomen, which he was told by a doctor was due to lead poisoning. This lasted more or less till Christmas, 1891, when pain in the "stomach" came on suddenly and "rheumatism" in the muscles of the leg. The tips of his fingers at that time became swollen, turning blue and red. He had been attending as an out-patient at this hospital since Feb. 16th, 1892. He did not think there had been much improvement, and he had lost three stone in weight since Christmas, 1891. He had suffered from rheumatic fever three years ago, from "rheumatism" three times since, and from influenza three years ago. He had also one "fit" last year; another a few weeks ago. The nature of these was doubtful.

On Sept. 16th the condition of the man was as follows: Extremely anæmic and emaciated; no blue line on the gums; tongue black (had been taking iron) and dry; fingers clubbed; pulse 68, soft; respiration not accelerated. Heart: Apex beat in the fifth space just inside the nipple line; dullness up to third rib. At the apex there was a loud systolic murmur heard also at the angle of the scapula. Over the pulmonary area there was an occasional systolic murmur; the second sound was accentuated there. Lungs: Great sinking in of supra-spinous fossæ behind; no dullness; no râles. Liver: Dullness up to sixth rib; not felt below the ribs. Spleen: Not felt; dullness not increased. Abdomen rather retracted and muscles held rigidly; nothing abnormal felt. Legs very wasted; wasting of the thenar eminences; no wrist or foot drop;

knee-jerks present, though slight; no impairment of sensation. Urine acid, sp. gr. 1012; a cloud of albumen; no blood.

Sept. 23rd.—Heart: Apex felt best in the fourth space one inch outside nipple line; distinct heaving impulse seen; systolic apex murmur louder. Has been gradually growing very drowsy; his mental condition is peculiar; he is continually whining, "I want to go home"; refuses food and will not wash himself, and acts generally like a refractory child.

24th.—Has been taking food properly since an attempted nasal feed.

30th.—General condition unaltered. Urine acid; sp. gr. 1018; thick cloud of albumen.

Oct. 2nd.—During the night he got out of bed, was put back again, and shortly became comatose, with Cheyne-Stokes breathing and dilated pupils. Death followed soon after. During his stay in the hospital the temperature was of a hectic type, ranging from 96·8° to 101° F. Usually there was a difference of two degrees between the morning and evening temperatures. He complained of thirst; the bowels were obstinately constipated; the respiration and pulse were never accelerated.

*Post-mortem examination.*—Brain: Both lateral ventricles were filled with a recent clot, which formed a complete cast of the right and anterior part of the left ventricle. In the right lateral ventricle there was a separate clot pushed to one side by the larger one, which appeared older than the rest, and was beginning to break down. There was also a blood clot round the medulla in the fourth ventricle and at the anterior surface of the pons and a small hæmorrhage over the superior frontal convolution of the right hemisphere. Lungs: Both bases congested and œdematous. Heart: Right side much dilated and thinned. Left side: Large vegetations all over the posterior wall of the left auricle. Nearly all the mitral valve was absent; what was left was much thickened (evidently of old standing) and covered with recent vegetations. Aortic valves healthy. One or two ulcers were present on the endocardium of the left ventricle. Weight eleven ounces and a half. Stomach and intestines normal. Liver rather enlarged with venous engorgement. Spleen much enlarged, reaching just across the middle line. Weight twenty-two ounces and a half. There were two triangular ischemic infarcts and one softer hæmorrhage. In the right kidney there were two infarcts; in the left three. The capsules peeled readily, and there were no signs of interstitial change.

*Remarks by Dr. TOOTH.*—The chief points of interest in the case are the following: 1. The difficulty of diagnosis. Chiefly owing to the history it was thought probable that he was suffering from acute anæmia after lead poisoning, although this did not explain the temperature. The question of ulcerative endocarditis was mooted, but no certain diagnosis was made. From the albuminous urine it was thought he had chronic nephritis. 2. There were no rigors or attacks of localised pain due to infarcts while in hospital. 3. His peculiar mental condition. In connexion with this it would be interesting to know the exact time the first hæmorrhage corresponding to the older clot took place. There was no paralysis or disturbance of sensation. 4. As regards the immediate cause of death by cerebral hæmorrhage, Dr. Bristowe<sup>2</sup> mentions one case under his care in which death resulted from effusion of blood into the substance of the brain, probably following an embolic aneurysm. 5. The clinical fact that, owing to various reasons—o.g., stomach resonance and rigid abdominal walls,—it is possible to fail to detect during life a spleen weighing twenty-two ounces and a half.

#### NORFOLK AND NORWICH HOSPITAL.

A CASE OF NEPHRECTOMY FOR CARCINOMA.<sup>1</sup>

(Under the care of Mr. CHAS. WILLIAMS.)

THE following is a description of a case of primary carcinoma of the kidney, and bears out the statement that primary carcinomatous tumours of that organ are usually of the encephaloid variety. The presence of the purulent collection in the upper part of the organ probably accounted for the pyrexia, and rendered the diagnosis from calculous

<sup>2</sup> Theory and Practice of Medicine, sixth edition, p. 674.

<sup>1</sup> An account of this case was read at the meeting of the Norwich Medico-Chirurgical Society, May 3rd, 1892.

<sup>1</sup> THE LANCET, vol. i 1885, p. 415 et seq.

kidney the more difficult. It is, however, always difficult to diagnose this form of tumour until the disease is far advanced, and, as the success of any operative treatment depends chiefly on the removal of the organ, it is advisable to publish these cases in some detail when they are met with, so that the earlier symptoms may be better known. The possibility of the coexistence of calculus and malignant growth of the kidney must not be overlooked, for "the liability to error is increased when gravel or small calculi are, as is not uncommon, present in the pelvis of the cancerous organ."<sup>2</sup>

C. T.—, aged fifty-eight, was admitted into the Norfolk and Norwich Hospital on the 1st of April, 1891, complaining of excruciating pain in the left lumbar region. She was the wife of a farm bailiff and was accustomed to hard work. Fifteen years ago she had a severe attack of sciatica of the left side; it lasted for several weeks, and had the effect of reducing her, from being a fine woman, to a mere skeleton. From this she never thoroughly recovered. Some nine years later symptoms of kidney trouble showed themselves, occasional pain being the most marked; still she was well able to attend to a large dairy and to maintain a fair state of health until twelve months ago, when she noticed that her urine was thick and sometimes stained with blood. A little later pain came on in the left loin and localised itself there and became very intense. Later still she was obliged to keep her bed and to take opium somewhat freely. Blood was now appearing in the urine in large and frequent quantity. The pain usually came on during micturition and lasted for some time afterwards. There was no definite history of renal colic.

On admission she was greatly emaciated, very pale and looked proportionately ill, her eyes being shrunken and her voice weak. In the left lumbar region there was a very distinct bulging outwards, which swelling was just as distinct in front, especially when she was placed on her back. This prominent substance—evidently an enlargement of the left kidney—was hard to the feel, very movable and extremely painful when touched, and so were the parts in which the cutaneous branches of the lumbar plexus ramified. She could usually pass the night without a desire to micturate, but when the feeling came on she was obliged to get rid of the urine as quickly as possible, however small the quantity might be. The urine was generally dark coloured and turbid, and sometimes for a few days was perfectly clear; when in this condition its specific gravity was 1020, and it contained neither pus, blood, nor albumen. There was no evidence of disease in any of the viscera except that connected with the diseased kidney. Her temperature rose every night for four weeks from 101°–102° and fell to about 99° in the morning. She had a brother older than herself who had for several years suffered pain in the situation of the left kidney and profuse hæmaturia at frequent periods; he had passed several small calculi. The severity of her pain, its constancy and localisation rendered it necessary to perform an exploratory operation, the more especially as the weight of opinion was in favour of calculus, and the patient herself desired that something should be done to mitigate her suffering.

The operation was performed on May 1st. An incision four or five inches in length was made along the left linea semilunaris; the thin omentum and collapsed bowels were pushed to the inner side and detained there by means of a flat sponge, the meso-colon pinched up and a small hole made in it and enlarged with the fingers. The kidney was now exposed to view; it looked healthy, but greatly enlarged. The hand was passed over the right kidney and ureter. Both were found to be of normal size and healthy. A needle was thrust into the substance of the kidney towards the pelvis; no stone could be detected. An incision was then made into the organ and enlarged with the fingers, but no calculus could be felt; the material did not feel like that of normal kidney, but was crisp, tore like hard carcinoma, which it unquestionably was. Nothing now remained but to remove the enlarged kidney; the pedicle was brought into view and two large branches of the renal veins exposed. A silk thread was passed around the whole—the kidney, artery, veins and ureter—which could not be separated from the rest. Another ligature was passed round the pedicle close to the kidney and the pedicle divided between. The organ was now removed from its bed. There had been very free venous hæmorrhage from the kidney. A large cavity was left; this was well irrigated with warm water and sponged out, a glass drainage-tube placed in the wound and the parts covered over with dressing. The kidney weighed thirteen ounces; its upper

third was apparently healthy, but the lower two-thirds had become converted into true carcinoma. The capsule over this portion was firmly adherent and thickened. The upper part of the ureter was enlarged to about the size of a small orange and contained from two to three ounces of thin, fetid pus. The pelvis seemed to be almost obliterated by the growth of the disease. At 9.30 p.m. the report was that she had had a good deal of pain in her left side, which the injection of one-sixth of a grain of morphia had relieved; she had been perspiring profusely. Her feet were warm; pulse 100. She was not restless. There was no abdominal pain. She had been taking some gruel and champagne. A teaspoonful only of blood-stained fluid was drawn through the glass tube.

The next day the account was that she had been fairly comfortable; the pain had been completely relieved by the morphia; there was no tympanites. A small amount of red-coloured serum was drawn from the tube. Pulse 100, of better volume. She took small quantities of food well. Urine had to be withdrawn and was clear. In the evening she was very comfortable. The temperature was 99°2', and there was no sign of peritonitis. Five ounces of urine were drawn off and about a drachm of fluid from the tube.

On the third day after the operation she was said to have passed a comfortable night, sleeping well and taking food. At about 4 a.m. she complained of abdominal and lumbar pain. This had been getting worse all day. The breathing was purely thoracic; there was no sickness, no hiccough. At 3 p.m. the pulse could scarcely be felt. The wound looked well; about half a teaspoonful of blood-stained fluid was withdrawn from the drainage-tube and eight ounces of urine were taken from the bladder. The abdominal pain increased in severity and she died the next day—the fourth from the date of operation.

At the post-mortem examination, made by Mr. Donald Day, the abdomen was slightly convex, there was no distension, the wound in the linea semilunaris was quite dry and the sutures firm; the wound opened easily; very little union had taken place. The abdomen contained about three pints of semi-purulent fluid, generally distributed over the cavity; a few recent adhesions were found. The glass drainage-tube passed directly through the lesser cavity of the peritoneum into the bed of the kidney. The wall of the cavity in which the kidney laid was lined with ragged black clots adherent to or in the meshes of the areolar tissue. No free clots or fluid blood were to be seen; the ligatures on the pedicle were firm and secure. No stone could be found in the ureter, which was of normal size. In front of the lumbar spine was a flattened, indurated lymphatic gland lying behind the vessels, nearly one inch in thickness and apparently a malignant infiltration. This was the only example of disease to be found.

*Remarks by Mr. WILLIAMS.*—This is the first nephrectomy that has been performed in the Norfolk and Norwich Hospital or in the city of Norwich. I have entered somewhat fully into the details of the case, especially in the description of the operation, inasmuch as the great question of the day is as to whether in these cases the surgeon should resort to the abdominal or the lumbar section. Dr. Gross, in an exhaustive paper on the subject, says that of 233 cases of extirpation of the kidney 129 recovered and 104, or 44·63 per cent., died. Of 111 by the lumbar incision, 70 survived and 41 died, the mortality being 36·93 per cent.; while of 120 by the abdominal incision, 59 recovered and 61, or 50·83 per cent., perished. He then observes: "It is thus to be perceived that the fatality of the abdominal operation is greater by 13·90 per cent. than that of the lumbar operation." If malignant growths be considered, of which he gives 49 cases, very much the same result obtains in each kind of operation. On the other hand, Mr. Knowsley Thornton, the most recent authority, up to 1889 had performed nephrectomy by the abdominal section in 25 cases: 20 recovered and 5 only died, a result 20 per cent. better than that generally given for all nephrectomies, including those by the lumbar section. Now Mr. Lucas claims a greater success by the lumbar. He has operated in six cases by the lumbar method and all the patients survived; but then this success was due to a judicious selection of the cases; not one was for malignant disease. Of the two kinds of operation I gave the preference to the abdominal, as being in every respect much the more suitable in this case. I had the same objections to the lumbar that Mr. Thornton has, and he gives seven. With such diverse opinions it is not surprising that nephrectomy should be looked upon with some degree of disfavour. No doubt the mortality has been increased by a selection of unfavourable cases or by delaying the operation too long. In

<sup>2</sup> Bristow: The Theory and Practice of Medicine.

my case the result would, in all probability, have terminated differently had the patient been operated on a year previously before her system became worn out by continuous pain, the more especially as the woman was free from disease in any of her organs, and only one lymphatic gland was found diseased. From what I have read of the details of the cases which have been published it appears to me that much of the want of success which has attended the operations performed up to the present time has arisen as a consequence of delay of the operation. As in tuberculosis, so in malignant neoplasms—a diagnosis made early and an operation promptly and efficiently performed are the elements of success. My friend Dr. Burton-Fanning sent me the following account of the examination he had made of some of the material: "The microscopical examination of the tumour shows it to be encephaloid cancer. The amount of stroma is rather unusually large, and it is arranged in a typical areolar fashion. The cells contained in its spaces consist of large and small round epithelial cells."

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

#### *Amputation through Thigh, preliminary to, or in place of, Amputation through Hip in advanced cases of Hip Disease.*

AN ordinary meeting of this Society was held on Nov. 8th, the President, Sir Andrew Clark, in the chair.

Mr. H. G. HOWSE read a paper on the Advantages of an Amputation through the Thigh, either as a preliminary operation to, or in some cases instead of, amputation through the hip, where the hip-joint was itself diseased and the patient in very bad condition. He took a case to illustrate the mode of treatment. In July, 1879, a boy aged fifteen had acute tuberculous osteitis of the left leg and the ankle-joint and early mischief in the left hip. He was very ill and emaciated, and had been going from bad to worse for three months. Amputation through the knee was performed on July 26th. Great improvement resulted, but suppuration in the hip necessitated excision of this joint rather later, from which he perfectly recovered. He left the hospital in June, 1880, and had remained quite well since. The position was advanced that much good might result in hip disease from amputation through the thigh: (1) by reduction of length of lever, having its fulcrum at the hip-joint, and so favouring rest; (2) by removal of a mass of tissue acting chiefly as blood-consuming and very little as blood-producing tissue, thereby probably favouring the production of blood of better quality and larger amount. Mechanical aids to rest were compared with nature's efforts by spasm of muscles fixing the joint. This spasm must be greater with a long than a short lever, and was probably an exhausting factor in the disease; much less would be required of the muscles controlling the hip-joint if the weight and length of the lever were lessened. In practice, after amputation above the knee, the immobility was so complete that no appliance was needed. If by this immobilisation the hip disease was not arrested excision might be successfully practised, as in the case in the text, the previous shortening making fixation easier; or amputation at the hip-joint might be required as in other cases, the patient's improved condition, resulting from the previous amputation and the slighter shock of the removal of a smaller mass of tissue, rendering this operation successful, though it would probably not have been so under the previous conditions. It was usual to explain the improved condition after amputation by the removal of diseased tissue with cessation of processes (pyæmia &c.) inconsistent with healthy nutrition; but the improvement after excision or arthrorectomy was not so marked, though the removal of disease should be as complete in the one case as in the other. The removal of so much healthy tissue, which used up instead of forming blood, was a more probable explanation. Alternative lines of treatment in the case the subject of the paper were reviewed:—1. When first seen, amputation at the hip would have resulted most probably fatally, or in a bad stump for an artificial leg. Excision was inadmissible with coexisting disease of the leg. 2. After amputation of the leg, amputation at the

hip would have left an inferior stump. The advantages to the patient were: (1) a stump more suitable for an artificial leg than any possible after hip amputation; (2) he was alive, which with other methods would have been improbable. This principle of treatment was applicable to a considerable variety of cases, as might be seen by examining the following list:—Cases: Group I.—1. Knee and hip disease on different sides; amputation of knee; great improvement in opposite hip; subsequent excision for relapse. Group II.—2. Amputation through the knee on the same side as hip disease; convalescence. 3. Amputation through the knee on the same side as hip disease; subsequent excision of hip; recovery (text). Group III.—4 and 5. Excision of hip, subsequently amputation through knee; convalescence. Group IV.—6. Excision of hip, subsequently amputation through knee and then through hip; recovery. 7. Phthisis and morbus coxæ; amputation through knee and subsequently at hip; recovery. 8. Old morbus coxæ; phthisis; lardaceous disease and rectal fistula; amputation through thigh; removal of rest of femur; improvement. Group V.—9, 10, and 11. Excision of hip and subsequent amputation through thigh in all; amputation at hip in two; all operative procedures carried out in safety; death in all from lardaceous or general tubercular disease.

Mr. LAWFORD KNAGGS then related two cases illustrating the treatment of Advanced Hip-joint Disease by Mr. Howse's method; of preliminary amputation near the knee. The method was indicated in cases of advanced hip disease when (1) excision had proved useless, or (2) when amputation at the hip would be too dangerous because of general feebleness or associated visceral disease. It offered a prospect of (a) retaining a portion of the limb, or (b) of saving a life that would be likely to be lost by other modes of treatment. Mr. Howse's method was to remove the limb by instalments. After amputation near the knee (first step) rapid improvement resulted, because (1) the amount of impoverished limb requiring nourishment was diminished; (2) there was greater freedom from pain from shortened leverage; and (3) as soon as the stump was healed patients were able to go out of doors on crutches. Finally, amputation of the shortened limb at the hip involved infinitely less risk in the improved condition than if carried out as a primary measure. The first case, a girl aged eight and a half, was the subject of advanced hip disease with much suppuration. The liver reached to the umbilicus. The urine contained one-fifth albumen, and amputation at the hip had been twice discontinued at consultations of the hospital staff as certain to prove fatal. After nine months as an in-patient, and when her condition was at its worst, amputation at the knee was performed on March 9th, 1888. This healed, and all her symptoms improved. The sinuses healed, and for three months the hip mischief was quiescent. It relapsed; Furneaux Jordan's amputation was done on Oct. 19th, and fragments of bone removed through an enlarged opening in the acetabulum. She left the hospital convalescent. In January, 1892, all sinuses had been healed for a year; the hip disease was quite well. The liver could no longer be felt. There was a trace of albumen, and her general condition and colour were very satisfactory. In the second case there had been progressive hip disease for two and a half years in a girl aged nine. Excision had been done eighteen months previously. Amputation at knee was performed on March 9th, 1888; great improvement resulted. In August, Furneaux Jordan's amputation was practised, and necrosed bone was removed through an enlarged opening in acetabulum. Sinuses resulted and albuminuria developed. Her condition in July, 1891, was otherwise satisfactory. Points of importance: (1) Freedom from pain after removal of leg; (2) the children, who had been bedridden a long time, were able soon to get out of doors and run about on crutches and make themselves useful; (3) the improvement in the hip disease; (4) the diminished severity of the hip amputation and the small size of the large vessels; (5) the opportunity for more complete exploration of the pelvis in consequence of diminished gravity of the amputation.

Mr. BARWELL said that the idea was new in surgery to perform a mutilating operation below the seat of a disease, leaving that disease *in situ*. Mr. Knaggs had mixed up two classes of cases. Those in which the procedure was a preliminary to the larger operation of amputation at the hip illustrated a point which had been much discussed by surgeons, but that was not the chief point of the paper, which was the question of the relief to the hip gained by amputation of the thigh. An analysis of the cases recorded

in both papers showed that there were five cases in which amputation had been performed as a preliminary operation in hip disease. One of these appeared to be convalescent without further operation, while in all the others some further procedure had to be adopted, and he did not think that this bore out Mr. Knaggs' statement as to the benefits derived from their method. Mr. Barwell held that amputation was not a proper remedy for checking the spasm of muscles controlling the hip; we should rather aim at perfection of apparatus for supporting the limb.

Mr. KEBTLEY said that seven years ago he published a paper having a superficial resemblance to those before them. His idea was that in a bad case of hip-joint disease the distal half and the proximate quarter of the limb should be taken away at an interval of about forty-eight hours. In considering the question of leverage, that applied externally should be estimated separately from that produced by the muscles themselves. He believed that the muscular spasm would continue to act just as unfavourably after the limb was amputated. He held that more shock was caused by an excision of the hip than by any amputation between the thigh and the hip, and he maintained that the proper order was first to excise and then, if necessary, to amputate. He concluded his remarks by criticising the alternative lines of treatment which Mr. Howse had appended to his paper.

Mr. R. W. PARKER said that he was in the habit of meeting with extremely bad cases of hip disease at the East London Children's Hospital among the poorest class of patients. It appeared to him that the patients were saddled with an extra difficulty if amputation were performed through the thigh and the hip and pelvic disease left untouched. The greatest difficulty in operating was the very excessive general oozing which occurred. After trying many methods he now adopted a modification of Furneaux Jordan's method—cutting down just above the knee, tying the artery and shelling out the femur. He then rapidly plugged the acetabulum, periosteal sheath and sinuses, and applied a bandage. Forty-eight or seventy-two hours later he opened up the limb again, took out the packing, removed all the disease that could be got at, freely irrigated, and then sewed up the stump, except at that part opposite the joint, which he left open for drainage. This gave him every advantage of Mr. Howse's method and much curtailed the hæmorrhage. The stump was far better than after the old operation, and a very useful lever was left for an artificial limb. In a case treated somewhat after this method by Mr. Shuter no new bone appeared to be formed; but in a case of his own a part of the femur had been reproduced, for, in treating a sinus later, he had cut down on the new bone. He had found that a hot-water mattress on the operating table materially warded off shock.

Mr. OWEN feared it was a dangerous doctrine to lay down that because a limb could not be kept at rest it should be cut off. He had found Thomas's splint and the stirrup and pulley both efficient to maintain rest of the limb. He referred to a case he had recently operated on of a boy in an advanced stage of hip disease, who was considered on consultation to be too ill to amputate at the hip-joint. He next day took the leg off above the knee and he intended later to make an incision along the side of the limb and shell out the femur.

Mr. DAVY so far coincided with Mr. Howse that if one could subdivide the procedure and make one huge operation into two lesser ones it would be better for the patient. His practice had been to excise first and amputate afterwards if necessary, and every case he had so treated had recovered. There were many ways better than amputation of securing rest to the limb. It was especially where pelvic necrosis existed that excision was to be recommended as a favourable and advantageous precursor to amputation at the hip, which might be afterwards required.

Mr. HOWSE, in reply, thought that many of the speakers had lost sight of the fact that these measures of treatment were not recommended for ordinary cases of hip-joint disease, but were only to be adopted in those extreme instances in which the only other alternative would be to leave the patient to die. His was precisely the class of case to which Mr. Parker had referred. He objected to the latter's method of operating that an enormous extent of periosteal sheath was left to increase the risk of sepsis, that the bleeding must be very great from such a wound, and that the shock was greater than that produced by amputation in the way he suggested. He objected to any one of the advantageous resulting conditions on which he had dwelt being discussed singly; they should all be taken together.

Mr. KNAGGS, in reply, called attention to the important fact that in the whole series there was no death as a result of the operation, and he felt sure that an equally happy result would not have occurred if all these bad cases had been submitted to primary amputation at the hip-joint.

## MEDICAL SOCIETY OF LONDON.

### *Tubal Moles and Tubal Abortion.*

AN ordinary meeting of this Society was held on Nov. 7th, the President, Mr. Hutchinson, in the chair.

Mr. BLAND SUTTON read a communication on Tubal Moles and Tubal Abortion, an abstract of which will be found in another part of our present issue. In illustration of his paper Mr. Sutton showed several pathological preparations and he made free use of the black board.

Dr. CULLINGWORTH referred to his now rather large experience of cases of tubal pregnancy. At a debate at the Medical and Chirurgical Society he had held that no man was justified in speaking of a case as one of ruptured tubal gestation unless some product of conception were found—embryo, amnion or villi. But he had since thought that in such a case as one of very early tubal abortion, where there were free bleeding and a large mass of blood in the peritoneum, one might fail to detect the very small products of conception. This was a case in which the history, the clinical and the pathological conditions favoured strongly a diagnosis of tubal gestation, although evidence of it might not be found. He asked if it were not possible for a Fallopian tube to become closed at its abdominal ostium upon clotted blood, the embryo and its immediate surroundings having escaped. If this could be so, it would introduce another element of difficulty into the differential diagnosis of hæmato-salpinx. He thought that it was at present impossible to limit the term "hæmato-salpinx" in the manner Mr. Sutton had suggested.

Dr. HORROCKS said that in cases where one could make out distinctly blood clot on the one hand and villi on the other the diagnosis was not difficult, but he held that cases were to be met with in which it would be impossible to distinguish one from the other, and he referred to one or two instances in support of this. Hæmato-salpinx, he thought, should be a general term, and it ought to include all cases in which blood was found in the Fallopian tube; it should be used, as pneumothorax was, independently of the cause of the condition, and he would include regurgitation of blood along the tube from the uterus, even if the tube were not distended by blood. He asked Mr. Sutton if he still maintained the same views as to the cause of the hæmorrhage, and he inquired if he regarded it as possible for the villi of the chorion to grow after the death of the embryo—his own opinion was that they did.

Dr. LEWERS wished to say a word or two as to the natural history of these cases of extra-uterine gestation. He believed that in many cases where the fœtus died at an early period complete recovery often took place without operation. Even when rupture had occurred, giving rise to pelvic hæmatocele, many of the cases did quite well under expectant treatment. He referred to a case of pelvic hæmatocele, due to rupture of an extra-uterine foetation, that had been under his care at the London Hospital some six years ago, and where he removed the fœtus through an incision into the posterior vaginal wall. This case did quite well, but he believed the patient would have recovered equally well without interference. At the same time he quite recognised that there was a class of cases requiring abdominal section, but it was often a difficult matter to distinguish between such cases and those that would do equally well without it. Evidence of the continued development of the gestation sac furnished a valuable indication.

Dr. HEXWOOD SMITH inquired of Mr. Sutton the exact source of the hæmorrhage when large in amount. He supposed that the blood was usually poured out before the ovum reached the end of the tube. Did the blood come from the ruptured attachment of the ovum or from the ruptured tube? He asked also as to the usual locality of adhesion of the ovum to the tube. He likewise desired to know in what cases one might expect tubal abortion and whether there was anything usually to account for it, such as an accident, a slip, a jerk, or the passing of hard faeces, dislodging the ovum.

Dr. ROUTII thought that all the cases of hæmato-salpinx, except a very few, were instances of tubal gestation. There

were always some of the preliminary symptoms of pregnancy and a decidua membrane was passed per vaginam, and the latter if found was conclusive of the nature of the case. He related a case of genuine hæmato-salpinx without gestation which occurred in a young girl. There was an imperforate os uteri, and after operation a large quantity of retained menstrual fluid of the usual character was evacuated. Three days later the patient died collapsed, and there was found hæmato-salpinx on both sides and one of the tubes had ruptured. These collections of blood in the tubes were quite shut off from the uterine cavity.

Dr. GRIFFITH confined himself to a criticism of small details. He said that Mr. Sutton formerly thought that the hæmorrhage which produced the mole produced the rupture. He (Dr. Griffith) asked him if he still held to this opinion. As to the mode of closure of the tube, a different explanation to that put forward by Mr. Sutton had recently been published in the *Edinburgh Medical Journal*, the longitudinal muscle fibres of the tube being held to be the effective agents in drawing the fimbriæ within the oviduct. Mr. Sutton had not referred to that variety of hæmato-salpinx caused by hæmorrhage from the mucous membrane of the tube itself. Dr. Griffith believed that regurgitation from the uterus was a very rare thing, the canal of communication between the uterus and the tube being very minute and of great length. Such regurgitation could only occur after very great distension of the uterus. He asked Mr. Sutton how he arrived at a positive diagnosis of the sixth or eighth week of pregnancy. Dr. Griffith held that the villi formed part of the fœtus, and it was extremely unlikely that they would grow after the death of the ovum. It was a remarkable thing that an extra-uterine foetation could go on to term, and that a proper blood-supply should be forthcoming in the absence of the maternal sinuses. He agreed that villi were not difficult to detect, but he had, as a rule, only observed one layer of short cubical epithelium upon them.

Dr. SUTTON, in reply, said that the main object of his paper was to give a careful account of these specimens so that others might be familiar with their external characteristics. After abortion or rupture of the tube the closure of the ostium would be deferred. He thought that the case related by Dr. Lewers was probably a hæmatoma produced by rupture of the gestation sac between the layers of the broad ligament. The dates of pregnancy he had given were approximate and were reckoned from the last period. He had examined a specimen of a well-formed mole in a tube without rupture and this had led him to modify his former belief on this subject. After the embryo died he felt sure there was no continued growth of the villi.

Mr. SHEILD showed a boy from whom, some time ago, he had removed the entire gracilis femoris muscle on account of a large pear-shaped tumour, which reached from the pelvis to the knee, and which he regarded as of congenital origin. A committee of the Pathological Society determined the growth to be a myxo-sarcoma. There was at present a small recurrence at the upper end of the thigh.

The PRESIDENT exhibited a series of interesting drawings, which he had borrowed, for the purpose of copying, from the museum of the Dublin College of Surgeons.

## PROVINCIAL MEDICAL SOCIETIES.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this Society was held on Nov. 1st, J. H. Bell, M.D., President, in the chair.—Dr. T. WHITESIDE HIME read a paper on his personal experiences of the cholera in Hamburg. The population of the affected area he computed as about 620,000, in which there were 18,000 attacks in six weeks and at the worst 1136 in one day. All arrangements, as, for instance, in regard to the disposal of the dead, were bound to break down under such pressure. On analysis the composition of the drinking water of Hamburg is found to be similar to, but about six times as concentrated as, the sewage effluent of Bradford or Leeds. The treatment by transfusion of a litre and a half of normal saline solution gave most astonishing results; and drugs, especially morphia, being more harmful than useful, calomel was given in minute doses, and hot tea and coffee as stimulants. Personally, if in cholera, Dr. Hime would like perfect rest, transfusion of a pint of normal saline extended over three-quarters of an hour, and then hot alcoholic drinks. There is no characteristic lesion found after death; the kidneys are dusky or livid, and the lungs generally collapsed

and full of infarcts. With regard to etiology, cholera will spare one place and attack another, which appears similar in regard to filth and unwholesomeness. It is found to avoid places on impervious granite or clay and to prevail on porous soils. The river has been lower in Hamburg this season than ever recorded. A prevailing epidemic of cholera is found to be true cholera by the presence of the comma bacillus; at first the cases are mild, later the disease increases in intensity. The water theory does not hold in the case of Hamburg, where the disease behaved as in a town with good water-supply, spreading from the poor and then to the rich.—After a short discussion by two or three of the members exhibits of a collection of pathological specimens from the Hamburg hospitals, and a number of histological preparations were made by Dr. Hime.

PLYMOUTH MEDICAL SOCIETY.—The opening meeting of the winter session 1892-93 was held under the presidency of Mr. Leah (Stonehouse) on Oct. 15th, in the Society's new library, Athenæum Chambers, and was devoted to the exhibition of cases and specimens.—Mr. PAUL SWAIN showed a woman aged twenty-two on whom he had operated five weeks before for the relief of Ankylosis of the Lower Jaw following scarlatinal arthritis. Tenotomy of the temporo-maxillary capsules had twice been performed in 1881, but with no permanent benefit. A triangle of bone was removed subperiosteally from each maxillary angle, an operation Mr. Swain believed to be the first on record of simultaneous removal on the two sides. The lower jaw had become arrested in development, the lower dental arch lying inside the upper, so that the teeth could not be separated. The mouth could now be opened one inch and a quarter and the patient masticated fairly.—Mr. LUCY showed a boy aged four on whom he had performed Macewen's radical cure for Inguinal Hernia eight months previously.—Mr. E. SQUARE exhibited a case of Double Facial Paralysis, probably syphilitic in origin.—Mr. BEAN brought forward a man aged sixty-two with Epithelioma of the Floor of the Mouth of six months' duration, with huge secondary growths in the upper cervical glands of the left side.—Mr. SWAIN showed a specimen of Fæcal Fistula which he had removed by Treves' operation, and reported that the result was very successful.—Mr. R. S. THOMAS showed the Bladder from a woman of fifty-two in which the trigone was the seat of a large epithelioma blocking the ureteral orifices, causing dilatation of ureters and renal pelvis, with subsequent suppression of urine, uræmic coma and death.—Mr. WOOLCOMBE exhibited (1) an Intestinal Collection of Cherry-stones and Straw removed by enterotomy; (2) a specimen of Meckel's Diverticulum having a free, rounded extremity.—Mr. BULTEEL showed an Ovarian Tumour recently removed successfully; and Mr. F. ROW handed round a photograph of a case of Ectopion Vesicæ.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of the Society was held on Oct. 27th, the President, Simeon Snell, F.R.C.S.Ed., in the chair.—Mr. SNELL introduced the following patients:—(1) A lad of nineteen, with extensive destruction of the face from Lupus. The right eye had been completely destroyed and the left was seriously implicated. (2) A child two and a half years of age, with a Chancre on the Left Upper Eyelid. (3) A baby with a small Nævus of the Orbit, and a young woman with a Nævus of the Plica Semilunaris of the Eyelid.—Mr. MAKEIG JONES (Wath) showed a married woman aged thirty-one with Exophthalmic Goitre who had consulted him four months ago for failing eyesight. He then found double optic neuritis and tremors of the right hand and arm. The right leg and the left arm were now affected by tremors, and there was paralysis of the right facial and right sixth nerve. Intense paroxysmal headache accompanied by vomiting was complained of.—Dr. GWYNNE showed a woman aged fifty-four suffering from Chronic Bright's Disease, who for a year and a half had well-marked albuminuric retinitis.—Mr. DALY JAMES showed the patient who was the subject of the paper on an "Unusual Case of Tuberculosis of the Skin" in the *Sheffield Medical Journal*. The disease had existed for nearly five years and had resisted very varied treatment, the diagnosis being doubtful. Since the publication of the case tubercle bacilli had been found in a nodule excised from below the knee.—Mr. DALY JAMES demonstrated his method of using Pick's zinc gelatine for threatened bedsores. The harder preparation was the one preferred. It could be removed by a hot sponge and replaced once in twenty-four hours.—Mr. MAKEIG JONES showed larvæ of a blow-fly which had been passed alive per anum by a patient. According to Dr. Beale larvæ of various blow-flies may pass

through the whole length of the alimentary canal in a living state.—Dr. BURGESS showed a suppurating hydatid cyst of the liver which had perforated the diaphragm, invaded the right lung and discharged its contents through a bronchus.—Mr. RICHARD FAVELL related a case of obstructed labour caused by fibroids of the uterus being engorged in the pelvic canal.

MIDLAND MEDICAL SOCIETY.—Mr. HASLAM, F.R.C.S., presided at the meeting of this Society on Oct. 19th.—Dr. G. H. MELSON showed a patient suffering from partial loss of urinary and rectal control, with increase of patellar and plantar reflexes, most marked on the right side where ankle clonus was also well developed. With this was paresis of the lower extremities leading to an equine character of gait, and the patient also exhibited the signs of general in-coordination. There was a well-marked history of syphilis ten years previously, and the present condition dated back altogether for eight years, many of the earlier sensory disturbances having cleared up almost completely.—Mr. HASLAM showed a large Sebaceous Horn that he had removed from the scalp of a woman aged fifty-six. It had been growing for six years, and measured along its curves eight inches and a-quarter, the greatest circumference was two inches and one-eighth, and the weight 480 grains.—Dr. MALINS showed:—1. A Fibroid Tumour occupying the body of the uterus removed by hysterectomy on Sept. 20th. 2. The Right Ovary and Fallopian Tube from a case of abdominal section. 3. A Unilocular Cyst of the Left Ovary. Patient aged forty-one, married, three children, youngest thirteen years.—Mr. HEATON showed an Aural Polypus, which he had removed by means of the galvano-cautery from a patient aged sixty, in whom it had been growing for eighteen years. The interest of the polypus lay in its size.—Dr. FOXWELL then read a paper on the Climatic Treatment of Pulmonary Phthisis.

MANCHESTER MEDICAL SOCIETY.—At the meeting of this Society, held on Nov. 2nd, when A. W. Stokes, M.R.C.S., presided, Mr. T. JONES gave the clinical history of three cases of Nephro-lithotomy, all terminating in recovery.—Mr. SOUTHAM mentioned two cases where Nephrotomy was performed for conditions attended by symptoms which closely resembled those of renal calculus, but in neither instance was a stone found. In one case the kidney was much contracted with an irregularly lobulated surface; in the other, where the symptoms developed shortly after an injury to the loin, it appeared to be in a healthy condition. In both cases the exploration of the kidney was followed by a complete subsidence of all the symptoms which were complained of previously to the operation.—Mr. WHITEHEAD gave particulars of three cases of Nephro-lithotomy. Two of them made rapid and complete recoveries; the third, some weeks after returning home convalescent, had a sudden attack of pain in the region of the kidney operated upon; an abscess developed and a sinus persisted many weeks, but eventually closed satisfactorily, and the patient had no further trouble.—Mr. G. A. WRIGHT made some remarks upon the surgical treatment of Hydro-nephrosis.—Dr. A. T. WILKINSON made some remarks on the bearing of Renal Disease upon the mortality of surgical operations. It appeared that in 26 per cent. only of the cases were the kidneys found healthy.

NORWICH MEDICO-CHIRURGICAL SOCIETY.—On Nov. 1st a large number of the members, having accepted the hospitality of the President (A. R. Manby, M.D.), were entertained at luncheon previously to the meeting to meet Sir Frederic Bateman and to congratulate him on the distinguished honour of knighthood so recently conferred upon him by Her Majesty the Queen.—The retrospective address was given by Dr. H. McCLURE.—Mr. CADGE read a communication from Sir Joseph Lister and ably advocated the claims of the proposed British Institute for Preventive Medicine.—Dr. BARNES (London) and other members of the Society took part in the discussion and it was decided to refer the matter to the Council for further consideration.—Dr. S. J. TAYLOR showed a boy suffering from Ectropion caused by a heloid growth of a scar following a burn of the face; and Mr. T. H. MONSE showed two specimens of Extra-uterine Fœtation removed by Abdominal Section.

PRIZE FOR A HUNGARIAN MEDICAL ESSAY.—The Budapest Medical Society offers a prize of a thousand gulden for the best work published next year in the Hungarian language on any subject connected with anatomy, physiology, histology, or experimental pathology.

## Reviews and Notices of Books.

*Diseases of the Eye: a Handbook of Ophthalmic Practice for Students and Practitioners.* By G. E. DE SCHWEINITZ, Professor of Diseases of the Eye in the Philadelphia Polyclinic. With 216 Illustrations and 2 Chromo-lithographic Plates. Pp. 641. Philadelphia: W. B. Saunders. 1892.

THIS work has been written by an accomplished surgeon who has had the advantage of the experience afforded by a large hospital, and has had the responsibility of the chapters on general optical principles and refraction taken from his hands by Dr. James Wallace, and of the section on Retinoscopy by Dr. Edward Jackson, the former of whom is the chief of the Eye Dispensary of the University Hospital, whilst the latter is the Professor of Ophthalmology in the Philadelphia Polyclinic. As a whole it corresponds to the works in this country of Berry, Juler and Swanzy. It is nicely got up, the print is good and the illustrations fair. Its chief defect is the absence of pathology. Even in the case of the diseases of the cornea, the pathological characters are very curtly dismissed. In passing we may just remark that Dr. De Schweinitz, in speaking of plastic operations on the cornea, is incorrect in stating (p. 278) that von Hippel is the originator of the proceeding of transplanting the cornea of the rabbit for the relief of dense central opacities. In reality, it was Himly to whom the merit is due, for as long ago as 1813 he proposed the operation, and it was practised by Heusinger in 1824, and shown by Thomé in 1834 to be feasible in animals.

The language is sometimes a little stilted, as when, in speaking of the pain in acute glaucoma, the author describes it as a "severe neuralgia of the trigeminal distribution," and in the next sentence remarks that in subacute attacks there is "a less marked similarly located pain"; a few pages further on he speaks of an operation as "entirely classical in its technique." He remarks that some difference of opinion exists in regard to whether the eye should be banded or not after iridectomy in glaucoma, and pronounces decidedly in favour of the application of a bandage, which he thinks should be applied for the first few days not only to the eye which has been operated upon, but also to the fellow eye, whilst the bandage that has been placed upon the affected organ should remain there until complete restoration of the anterior chamber has taken place by healing of the wound. He adds, it is a "wise precaution to instil eserine into the eye which has not been operated upon during the course of the treatment."

The subject of glaucoma is, however, carefully and fully given; the usual divisions of acute, subacute, chronic, secondary hemorrhagic, and complicated glaucoma are each described. The various theories of the etiology of the disease—as those of von Graefe, Donders, Knies and Weber, Priestley Smith, Laqueur and Brailey—are all briefly discussed and their value estimated. This is as it should be, for, with the exception of purulent ophthalmia, there is probably no single disease of the eye which it is more important that the general practitioner should be competent to diagnose and treat.

In considering the treatment of cataract Dr. De Schweinitz mentions, whilst he cautiously abstains from recommending, the artificial ripening of cataract. The account of the operation for extraction is well given, and as the details include iridectomy we suppose that the author prefers that method, though, as he observes, many operators in America as well as in this country are disposed to omit that proceeding unless special circumstances call for its execution. The subject of refraction generally and the account of astigmatism in particular, together with the mode of relieving it by glasses, are very well done, and the following may be taken as

an example :—“The combination of a convex spherical lens with a concave cylindrical lens has the following effect :— In the direction parallel to the axis of the cylinder the combination equals the full refraction of the spherical ; in the direction at right angles to the axis of the cylinder the refraction is equal to the difference between the two lenses. If the convex spherical is stronger than the concave cylinder the difference is still represented by a convex glass. For example, + 2 D spherical c - 1.50 D cylinder axis 180° = + 0.50 D spherical c + 1.50 D cylinder axis 90°, because + 2 D in the meridian of 180° is not diminished, but in the meridian of 90° it is reduced to + 0.50°. Now + 0.50 D spher. produces this amount of refraction at 90° and supplies + 0.50 D of the requisite + 2 D at 180°, leaving + 1.50 D to be supplemented by a cylindrical lens with its axis at 90°. In place of writing + 2 D spher. c - 1.50 D cyl. axis 180°, a more simple expression would be + 0.50 D spher. c + 1.50 D cylinder axis 90°”; and then the case when the concave cylindrical lens is stronger than the convex spherical is considered. The chapter on operations might with advantage be extended. The practitioner who had never seen the operation performed would hardly be able to undertake the operation of tenotomy from the instructions here given ; whilst in regard to readjustment Swanzy's method is alone intelligibly given ; Prince's and Schweigger's methods, though mentioned, are too briefly described to be of any service. In conclusion, we may observe that Dr. Schweinitz's treatise is very reliable, and may be consulted with advantage both by the general practitioner and the ophthalmic surgeon, whilst it will prove a very useful book to the student.

*Garden Design and Architects' Gardens.* Two Reviews Illustrated, to show, by Actual Examples from British Gardens, that Clipping and Aligning Trees to make them Harmonise with Architecture is Barbarous, Needless and Inartistic. By W. ROBINSON, F.L.S. London : John Murray.

In these days, when public parks and open spaces are felt to be necessities for dwellers in towns, Mr. Robinson's little book will possess an interest for many who frequent them and who may thus gain some insight into the mysteries of landscape gardening, from which they were formerly in a large measure debarred. Everyone cannot own country seats or extensive grounds, but anyone can admire and enjoy beautiful gardening in public places. Mr. Robinson speaks strongly of the “false” and “inartistic” treatment of trees, which are often clipped and shaped in various fashions without any valid reason. He also deplors the sacrifice of many lawns and stretches of turf which are cut up into geometrical shapes, leaving no room for a broad and comprehensive effect, or for the use of games or enjoyment. The book is full of beautiful illustrations taken from some of the most noted gardens in England and elsewhere. The author complains that the work of the landscape gardener is often more like that of an engineer than of a keen student and lover of nature. The book is clearly written, and should be readable even to those who know little about gardening as an art.

*Dictionary of National Biography.* Edited by SIDNEY LEE. Vol. XXXIX.—Lambe-Leigh. London : Smith, Elder and Co.

THE publishers of this elaborate work are to be congratulated on the promptness with which each succeeding volume is put before the public. We do not in this place attempt anything like criticism of the merits of this biography. This must be reserved until the completion of the work. Meanwhile it may be interesting to recall a few incidents in the lives of medical men whose names occur in the volume just issued.

Brown Langrish, M.D., F.R.S., who died in 1759, was an

author of some distinction. His writings included a work entitled “The Modern Theory and Practice of Physic,” and another on “Physical Experiments on Brutes”—experiments undertaken in order to devise “a safe and easy method of dissolving stone in the bladder.” The Croonian Lectures on Muscular Motion were delivered by him before the Royal Society in 1747.—Christopher Langton, M.D. Camb., who died in 1578, published a book with the quaint title, “A Very Briefe Treatise orderly declaring the Principal Partes of Physick—that is to say, thynges naturall, thynges not naturall, thynges agaynst nature.” Langton appears to have been a man of considerable intelligence, but somewhat deficient in moral stamina.—The name of Dr. Edwin Lankester, who was born in 1814 and died in 1874, comes next, and deserves a somewhat fuller notice than that given to either of the above. Originally intended for the career of an artificer, his taste led him subsequently to seek access to the medical profession, and as surgical assistant he entered the service of Mr. Staniland of Fareham. In that position, however, he did not long remain. He felt himself in the possession of abilities equal to a more distinguished rôle. Accordingly, having entered a medical course in the London University, he pursued with ardour the studies fitting him for his future work until he was enabled successfully to compete for the qualifications M.R.C.S., L.S.A. Repairing to Heidelberg, he obtained the M.D. degree, and afterwards settled in London, and supported himself by literary work, popular lectures and such practice as fell in his way. On the death of Mr. Wakley, M.P., Dr. Lankester was elected, after an exciting contest, to the Middlesex coronership, a post the functions connected with which his predecessor had done so much to exalt in public estimation, and into whose labours Dr. Lankester entered with enthusiasm. His contributions to science by both tongue and pen were of no mean order.—Several celebrities of distinction owning the name of Latham figure in this volume.—Dr. John Latham (1761–1843) studied medicine at St. Bartholomew's Hospital, and began practice in Manchester, but soon removed to Oxford, where he became physician to the Radcliffe Infirmary. Afterwards he came to London and was elected physician to the Middlesex Hospital. In 1795 he was appointed Physician Extraordinary to the Prince of Wales. He delivered the Gulstonian Lectures in 1793, the Croonian in 1795, and occupied the presidential chair from 1813 to 1819 inclusive. He was a voluminous writer.—Dr. Peter Mere Latham, son of the above, was quite as distinguished as his father, though his reputation as a physician does not seem to have attracted so large a *clientèle*. His clinical teaching was regarded as excellent, and his writings (especially his Lectures on Clinical Medicine, comprising diseases of the heart, which for long will remain a standard work) are not likely to pass into oblivion. He was appointed Physician Extraordinary to the Queen in 1837.—Robert Gordon Latham, M.D. (1812–1888) is chiefly known as an ethnologist and philologist, and as the editor of Johnson's Dictionary. He was formerly lecturer on *Materia Medica* at the Middlesex Hospital, but in 1849 he abandoned medicine in favour of his ethnological studies.—Of Dr. Thomas Lawrence, who occupied the position of President of the Royal College of Physicians in 1711–1783, there is not much to be said. He appears to have been noted chiefly for the writing of elegant Latin and as the author of the *Life of Harvey*, prefixed to the College edition of his *Opera Omnia*, for which Lawrence received £100.—Sir William Lawrence, F.R.S., the famous surgeon of St. Bartholomew's Hospital (1783–1867) demands a somewhat more detailed notice. His professional career commenced by Abernethy appointing him his demonstrator of anatomy. After his admission to the Royal College of Surgeons he became assistant surgeon to St. Bartholomew's Hospital, to the full surgery of which institution he was appointed in 1824, an office he held for forty-one years. His lectures, delivered at the College of

Surgeons, on Comparative Anatomy and Physiology roused at the time of their publication a good deal of odium, and Lord Eldon refused an injunction to protect the rights of the author on the ground that they contradicted the Scriptures. Those times have now happily passed away. Lawrence was described by his contemporaries as an admirable lecturer and clinical teacher. His commanding presence, great experience and sagacity made him venerated not in medical circles alone, but in society generally. A notice of his life would not be complete without a reference to his attack on the management of the College of Surgeons, an opposition which, however, says his biographer, was afterwards warded off by the Council electing him a member of their board.—Of John Leake, M.D. (1729–1792), little need be said, and that little seems to be not of a highly reputable kind. He described a new kind of forceps having three blades instead of two, but the device was not received with favour by the more experienced obstetricians. He published some works on diseases of women, but addressed his remarks in two instances, at least, not to physicians, but to women themselves.—Arthur Leared, M.D., born in Wexford in 1822, obtained his doctorate in Trinity College, and, having practised for a short time in the above-mentioned town went to India, where, however, his health did not permit him to remain. Dr. Leared diligently improved the opportunities afforded him by travel, and, being apt in the acquisition of foreign languages, managed to obtain very wide culture. His society was therefore much sought after by the learned and artistic. His writings were numerous, the most important of them being perhaps his treatise on “Imperfect Digestion” and on the “Sounds caused by the Circulation of the Blood.” He died in 1876.—Edwin Lee, M.D. Gött., entered the profession as an articulated pupil of the Royal College of Surgeons of England and became a member of the medical staff of St. George's Hospital in 1824. His chief strictly professional subject was lithotrity, for which he gained the Jacksonian prize. He resided much abroad, and was best known for his numerous handbooks of continental travel.—Another physician of the same name (Robert Lee, M.D.), an obstetrician of great eminence, must be mentioned. His life was embittered by the disregard paid by his contemporaries to his discoveries of the nerves of the uterus, the reality of which, as described by him, was disputed by other distinguished anatomists. A long list of papers and memoirs bearing on kindred subjects was published in THE LANCET of March 22nd, 1851. That Robert Lee was an able anatomist cannot be questioned, but whether all his conclusions and observations will survive the results of further research must await the verdict of posterity. His preparations and specimens are now lodged in the museum of Cambridge University.

*Glanders: How it Arises and Spreads &c.* By W. HUNTING, F.R.C.V.S. London: H. & W. Brown. 1892.

IN a sixpenny pamphlet Mr. Hunting attempts to deal in a popular manner with the subject of glanders, which has occupied a fair share of attention lately. There is, of course, nothing new in his statements or proposals so far as sanitary measures are concerned, neither is there anything to interest the pathologist in the few pages devoted to the consideration of the causes and symptoms of the malady. The author ascribes the prevalence of the disorder to ignorance on the part of horse owners, but surely his long experience must have taught him that in a large number of instances in which diseased horses were kept alive for days, weeks, and even months together, and even worked when there was small chance of detection, the owner was perfectly cognisant of its existence. In the large studs of horses which are infected in London the nature and symptoms of the disease are well known to the proprietors, and yet there is often

hesitation in reporting cases. It is proposed to give compensation for the slaughter of diseased horses in order to induce owners to notify its existence and obviate concealment. If its prevalence is due to ignorance, then compensation would not do much towards revealing it. Indeed, the author gives striking instances adverse to his statement, especially when treating of compensation. It is satisfactory to note that the writer does not believe in the curability of farcy, though we believe he has asserted elsewhere that a farcied horse could be permanently cured. Infection through the medium of the atmosphere he denies, because the glanders poison, he states, is not volatile; yet he admits that the lungs are always affected in developed cases. Some of the best authorities are of opinion that, under certain circumstances, glanders may be communicated through the atmosphere, as in hot, foul stables, and on the main and lower decks of ships when the temperature is high, as when the hatches are battened down. It would therefore not be wise to neglect this probable cause of spread under all circumstances. Mr. Hunting does not attach much importance to the danger usually ascribed to public drinking troughs, though he does not quite deny the possibility of infection sometimes occurring in this way. He says that “tramway, omnibus and cab horses suffer most from glanders, and yet the majority of these animals never approach a public trough. Small carters and carriers are the greatest patrons, and they hardly ever suffer from glanders amongst their horses.” It is true that tramway and omnibus horses do not drink at these troughs, but they do so at those of their own establishments; cabdrivers, however, largely avail themselves of the public troughs, and there is much evidence—that of the Brown Institute, for instance,—to show that the horses of small owners very often suffer from the disease.

With many of the author's statements we must disagree, so far as getting rid of the disorder is concerned. He remarks, for example, that he would expect the virus to lose its potency in a damp stable in a few days; and that he does not believe it will remain active, even in a dry form, for more than six weeks. We can call to mind a very serious outbreak among horses in the east of London, due to putting them into an old wooden, badly ventilated, and worse lighted stable which had been shut up for more than twelve months, and which had been disused during that time because many cab-horses had perished in it from glanders. Another serious mistake we consider the author makes is with regard to the floors of infected stables, which he believes to be the least worthy of notice. “The worse the flooring, the more moisture and decomposing matter we find on it and in it, and these conditions are themselves inimical to the preservation of glanders poison.” Such a statement will not, we feel confident, receive the countenance of anyone who has had to deal with the disease for any length of time, and we should be sorry to act upon it if we were called upon to stamp out an outbreak.

There are many other remarks to which exception could be taken, but we have said sufficient to show that some of the opinions expressed are not quite in harmony with those of others who have had experience of glanders. Indeed, had the pamphlet not been intended for the general public we should not have felt ourselves justified in giving it such a lengthy notice. But as the author is the veterinary inspector for Westminster and Chelsea any statements he may make might be accepted as indisputable and perfectly reliable, and in this way lead to serious mischief if they were not so. The author is also not quite up to date, though the *brochure* was recently issued—the preface is dated September of this year. Among other things there is no mention whatever of mallein as an aid to diagnosis, though that valuable substance was in use more than a year ago.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 12, 1892.

THERE is probably no better criterion of the state of medical science and of the medical profession of a country than is supplied in the proceedings and the discussions of its medical congresses. This is as true of a colony as of the mother country. We have lately had the opportunity of applying this test to our Australasian colonies, so far as such proceedings and discussions can be judged by newspaper reports. It is gratifying to be able to say that, judging from this test, the profession in our Australasian colonies will bear a favourable comparison with the profession at home. The third session of the Congress opened in Sydney on Monday, Sept. 26th, at 11 A.M., in the Great Hall of the University, and it must have been an imposing event. The Australasian colonies number, we suppose, about 4,500,000 subjects, without counting the aborigines. The roll of the Congress numbered 534 members, drawn almost entirely from the colonies themselves. This is no bad muster in itself for a population about equal to that of London. It is interesting to know the contribution to it of the several colonies: Sydney itself sent 208; New South Wales, outside Sydney, 111; Victoria, 131; South Australia, 39; Queensland, 32; New Zealand, 12; Tasmania, 11; and Samoa, 1. One more was supplied by New York. The Congress received full recognition of its importance by the presence of the Governor, the Earl of JENSEX, and the Premier, Sir GEORGE DIBBS, K.C.M.G. Both these distinguished men gave a hearty welcome to the Congress, and the Premier enumerated various measures in sanitary legislation which he had promoted and others which he had in contemplation, mentioning that Dr. McLAURIN, now in England, was authorised by him to gather all information in Europe that would help in a comprehensive Health Act. The Governor entertained the Congress at a garden party at the Government House, and nothing indeed was wanting in the way of hospitality, and excursions, scenery and weather, and general good humour to give dignity and effect to the Congress, which reflected the highest credit on all concerned. A little point was raised at an evening meeting as to the mode of electing the executive in such congresses. The mover of a resolution, in itself reasonable enough and supported in a temperate speech, did not succeed in carrying it. It is always wise in such arrangements to consult as much as possible the general feeling of the profession of the district which is to receive and entertain the Congress. But there are various ways of doing this, and it does not seem to have been left undone in the present instance, if done somewhat differently from the way suggested by Mr. TARRANT. Excepting this incident the proceedings were of a most satisfactory character. So much internal harmony and so much hospitality from the representatives of the State go far in themselves to justify the Congress and are a sufficient reason for such gatherings; but the justification is greatly strengthened in this instance by the nature of the proceedings. The address of the President—Dr. P. SYDNEY JONES—was in admirable

taste and spirit. It consisted of an exposition of the progress of medicine during the past forty years, the period covered by Dr. JONES'S own experience since he began the study of medicine at University College. It was meant to rebuke and remove that spirit of doubt and scepticism as to the progress of medicine which so many minds seemed to cultivate, and very ably did the President establish his contention that the progress of both medicine and surgery in this period had been simply marvellous. No part of the great subject was omitted—from anatomy to pathology, from the treatment of wounds to the latest improvement in pharmacy, from cases showing the cure of tuberculosis to the achievements of preventive medicine. In the various sections there was the same proof of progress in the interest taken in every branch of medical work. We publish elsewhere an abstract of the proceedings. In the Surgical Section cases were read which illustrated the most brilliant triumphs of careful operation guided by the latest helps of advanced physiology. One case of excision of the pylorus for scirrhus, extending two inches into the duodenum, was exhibited, in which the patient, after two years, was in perfect health. Tracheotomy in diphtheria was reported as successful in fifty of one set of 120 cases, and ten of another set of thirteen. In some of the sections only half the cases could be read. Important discussions were opened on the subject of anæsthetics.

We cannot pretend to even mention the many valuable contributions in all the Sections. From our abstract elsewhere our readers will see that the lights of medicine burn brightly in the Australasian colonies. We receive occasionally discouraging reports of professional methods and manners from these colonies, but we are reassured by the Congress and convinced that the high character and aims of the profession are well sustained in Australasia.

FROM the reformer's point of view the proceedings at the ninth annual general meeting of Fellows and Members of the Royal College of Surgeons of England, held on the 3rd inst., may be regarded with satisfaction and complacency. A few skirmishes enlivened speeches which were inordinately long, and dull withal at times, but there was no very serious antagonism between the militant Members present at the meeting and the authority of the President, who occupied the chair. Having given a fair and useful summary of the report which had been placed in the hands of the Fellows and Members, the President desired the assistant secretary to read the following resolution, of which notice had been given by Mr. LAWSON TAIT and Mr. NELSON HARDY: "That this meeting of the College of Surgeons of England is of opinion that the report now presented is ineffectual and incomplete, and this meeting is further of opinion that the ancient attitude of hostility on the part of the Council to the true interests of the body corporate of the College ought to terminate, and that the repeated resolutions passed at former meetings of the College should be carried into effect."

This resolution had already been before the President, and had received his sanction after it had been amended by Mr. LAWSON TAIT, at his request, by the excision of words referring the report back to the Council. The resolution was therefore strictly in order, and on several grounds it would have been better to allow Mr. TAIT to proceed and to hear

what he had to say before making any comment. The President, however, intervened between Mr. TAIT and the motion by suggesting that he should divide his motion, characterising it generally as offensive, and throwing out a hint to the meeting that it should not be put or even discussed, and, failing this resource, he proceeded to rule that the resolution *must* be divided. This ruling Mr. TAIT accepted under protest, saying "he knew of no meeting conducted in such an extraordinary fashion as this. He had never heard a chairman argue a resolution before the opener had spoken, and he had never heard of any business body in the world beginning a meeting as this meeting had begun. The resolution had been accepted in the course of correspondence, and if it was now to be amended he considered that there had been a breach of bargain." He then addressed himself to the first clause of the original resolution, that the report was ineffective and incomplete, referring to the exclusion of the Society of Apothecaries from all consideration in the scheme for the five years' curriculum, to what he considered to be defects in the scheme itself, to the want of consultation of the body corporate of the College in regard to the proposed new University for London, to the want of full information in regard to the extraordinary expenditure at the College and to some minor defects and omissions. In seconding the motion Mr. NELSON HARDY specified a misprint in the report which would go down to posterity and made an effective point out of the fact that throughout the whole of the report the words "Council" and "College" were used in such a way as to lead the reader very often to believe that the Council was the College, or, on the other hand, that the College was the Council. Both Mr. HARDY and Dr. DANFORD THOMAS dwelt on the ineffective and incomplete replies received from the Council in answer to the resolutions passed by the Fellows and Members for many years. Mr. GEORGE BROWN having supported the resolution and Mr. CRAVEN and Surgeon-Colonel INCE having spoken against it, Mr. HOLMES expressed a feeling prevalent at the meeting that, as the constitution of the College stood, the report was a very satisfactory one, and he regretted that the report which had been drawn up in a spirit very friendly to the Members and Fellows should be spoken of in terms which he could not help regarding as somewhat disparaging. The intervention of Mr. HOLMES, who was warmly cheered on rising, secured the defeat of the first part of the resolution, that the report was ineffective and incomplete; and we believe that if the President had not insisted on the resolution being divided the resolution as a whole would not have been carried, because those who disapproved of the first part of the resolution—the majority of the meeting—would have abstained from voting for a resolution weighted by a clause with which they could not concur. The moment, however, the incubus was removed the latter part of the resolution, moved by Mr. LAWSON TAIT and seconded by Dr. ALDERSON, regained its elasticity, and, notwithstanding the appeals of Surgeon-Colonel INCE and the President of the College, was carried by a large majority. We agree, however, so far with the President that this resolution might have been expressed in language less open to exception as apparently offensive: for whatever opposition the Council has offered to enfranchisement and representation of the Members of the College has been due at least to a con-

viction that measures of this kind would not be for the welfare of the College, which they have regarded too exclusively as a scientific body; and in this the Council have been supported strongly by the main body of the Fellows, who have regarded the pretensions of the Members with disapproval and apprehension. The Council must of necessity reflect the opinions of the constituency who elect it, and therefore it is that if justice is ever done to the Members it must come in the first instance not from the Council, but from the Fellows themselves. Many of the Fellows are already convinced of the expediency of making concessions to the Members of the College, and in proportion to the increase of privileges granted to the Fellows and to the open discussion of collegiate affairs at meetings of the Fellows summoned by the Council will be the growth of liberal opinion in their ranks. We are not sure that the Members of the College are fully convinced of this, for immediately after Mr. LAWSON TAIT'S motions had been disposed of there was a large exodus of Members from the general meeting before the resolutions promoted by the Association of Fellows came on for discussion. It is gratifying, however, to be able to record that both of these resolutions were almost unanimously passed. On the motion of Mr. HOLMES and Dr. DANFORD THOMAS the meeting thanked the Council of the College for acceding to their wishes in the matters (a) of separate meetings of Fellows and Members, and (b) of the provision of a common room in the College. Mr. HOLMES pointed out most appositely the great importance attached to separate meetings of the Fellows by those who had urged them on the Council, because they had strong opinions as to the undesirability of maintaining the present constitution of the College, and as to the desirability of some modifications of the Charter, and because the opinions of the Fellows generally both on these points and on the claims of the Members would be obtained in a manner more satisfactory than had been done by a paper which the Council had circulated some years since. Curiously enough, Mr. LAWSON TAIT was the only person who held up his hand against the motion. The last resolution, moved by Mr. GANT and seconded by Mr. JOSEPH SMITH, ran as follows: "That this meeting of Fellows and Members again wishes to impress upon the Council that it is absolutely essential for the welfare of the College that the Fellows and Members should be consulted before any change is made in the constitution and external relations of the College and before the College is committed to any extraordinary expenditure on buildings or otherwise."

It will be noted that there are three different things specified in the resolution as to which the expediency of consulting the Fellows and Members is insisted on: changes in the constitution which can only be effected by Charters and By-laws, the external relations of the College—such as those with the College of Physicians, Universities and the Apothecaries' Society—and extraordinary expenditure. The President appeared anxious to set aside the resolution on the ground that consultation in regard to larger questions had been admitted by the Council in an answer in 1885 to certain resolutions passed by the Fellows and Members. But such larger questions included some only of the points raised in the third resolution, and an admission of the principle by the Council in the form in which it is embodied is by no

means sufficient to bind the Council hereafter. Moreover Mr. LAWSON TAIT hit the nail on the head when he remarked that he had seen little disposition in the Council since that memorandum was issued in 1885 to take advantage of this resolution. Hence it is of the greatest moment to the cause of collegiate reform that the principles laid down in the third resolution should have been reaffirmed at a general meeting and have elicited from the President of the College a statement that the Council recognised the justice of the principles and intended to act upon them. We shall look with the greatest interest for the answers which the Council will give to the resolutions passed at the ninth annual general meeting of Fellows and Members, and by these answers the progress of the reform movement may in all probability be most accurately gauged.

THE second of a series of articles in *The Times*, dated Nov. 4th, on the subject of "English Ports and the Cholera," revives a question to which most people thought *The Times* had itself in previous articles, and notably in those of Aug. 27th, Sept. 3rd and 24th, given its death-blow—namely, that of maritime quarantine against cholera. The writer having dealt with defects in our ports, which are, we fear, but too abundant, goes on to refer to the reiterated demand for quarantine. He states that, to most of us, arguing about quarantine seems like flogging a dead horse; but having given it as his opinion that "it is not dead yet," he further declares that the demand for it "is not so foolish as it looks." He also points out that the request of certain authorities is that in the case of ships making short voyages of from thirty to fifty hours they should "be isolated for a couple of days so as to give cholera time to show and so prevent its introduction ashore." It is true that he adds that we have abandoned quarantine for good and that "no more need be said about it," but unfortunately the little he has said is to declare that for England the system is not so foolish as it looks, and the authority of *The Times* for such a statement is one that will certainly be utilised both at home and abroad in antagonism to the views which have been enunciated for some forty years past on the part of the British Government, and which have recently been renewed with a decision that leaves little to desire.

The suggestion which the special correspondent of *The Times* does not regard as foolish is that as respects ships from infected ports, and on which "no one is visibly ill," a detention of forty-eight hours should be added to a fifty hours' sea voyage, making four days in all between leaving the infected port and permission to land in an English port. Is this different in principle from the "five days' quarantine" which foreign nations imposed on our shipping when cholera was present in several of our ports a little more than a month ago and which *The Times* then declared to be "a crowning absurdity"? Cholera prevailed close to Boulogne a short time since; it may at any moment next year prevail in ports such as Boulogne, Calais and Dieppe. Does the writer of the recent article propose that notwithstanding the powerful arguments as to the absurdity of any such scheme which *The Times* advanced on Sept. 24th, the passenger traffic from these ports should be subjected to a forty-eight hours' detention—a proceeding under which,

as *The Times* has well put it, English harbours and rivers "would be choked with vessels containing ..... passengers for whom there would be no accommodation ....."? And if passengers merely sailing from such ports as have been named are to be subjected to this detention, what about those who come from "an infected place"—Paris, to wit—where cholera has been widely prevalent both in 1884 and in 1892? We are sure the system is quite "as foolish as it looks," and this mainly because it cannot be carried out.

But, insists the special correspondent, we ought also "to put ships from infected ports at short distances on the same footing as ships actually infected." Here, again, we are face to face with an interference with a traffic between France and England which at one time during the recent prevalence of cholera amounted to not far from a thousand passengers a day. It would be interesting to know what the Dover Town Council would have to say to this, and where in a gale of wind the unfortunate ships and their complement of passengers would be placed. Our merchants who import butter and fruit from Brittany and the neighbourhood would doubtless also wish to have something to say concerning this proposal, and they would, we expect, appeal to *The Times* itself as to the "cruelty to individuals," and as to the useless interference with the importation of "the fruit, the vegetables, the eggs, the butter, and so on," which that journal has so graphically described.

The theory of "local option" has acquired some prominence in recent years, and it might become a question whether those who do not regard quarantine detentions as foolish should be allowed to do as they like with their own ports, whilst an absolutely impossible and impracticable duty should not necessarily be cast on all other ports. This, we know, would not be at all pleasing to some such ports as Grimsby. They may wish to keep fish from the North German coast out of their port, but not at the risk of its being passed on to another port, and so finding its way into the disinfecting apparatus of English domestic life—namely, the cook's fish kettle—by a new route. Were it not for this view it might be practicable to let ports do as they wish in the matter, for they could then also decide what constitutes an "infected port"—a term which no English Government has as yet undertaken to define. But this point, too, has already been decided in a statesmanlike way by *The Times* when it was condemning resort to any such system. "It is obvious," says that journal, "that one and the same system must be applied to all British ports." This, too, is the view of the special correspondent, who is otherwise the mouthpiece of an opposite contention. He would impose the detention of vessels everywhere and not even allow a discretion to the medical officer of health. "You must do it" is the action which he proposes to be applicable as much to Dover as to Grimsby.

We cannot help thinking that these views of the special correspondent and of those port authorities who advocate quarantine detentions, whether of two, four, or seven days, are based on a failure to apprehend one essential point which underlies our English system of cholera prevention. It is very generally thought that those who support our system of "medical inspection" as opposed to quarantine detentions pretend that the system will absolutely suffice to keep cholera out of the country. This is the reverse of that which is con-

tended by those who are responsible for the inauguration and the future development of the system. On the contrary, they hold that whilst our port sanitary administration ought to be organised on a basis and scale sufficient to serve as a first line of defence, it is, after all, on the improved sanitary circumstances of England and Wales as a whole that we must rely to prevent the spread of imported cholera. The port districts are expected to do their best, and this best will under the English system be infinitely more efficacious than a system of quarantine detentions; but after they have done their best precisely the same is expected of the inland districts. This, too, has been the main strength of our English system of sanitary administration, for it has been largely due to the knowledge, in the face of previous epidemics of cholera, that such detentions as are suggested are impracticable under the circumstances of this country, and will hence not be attempted, that such large and remunerative disbursements have been made for the purposes of public health. We think it most helpful that the defects of our ports and inland districts should be exposed, but we trust that no encouragement will, in view of the actual facts which we have to face, be given to those who advocate quarantine detentions in connexion with the general traffic coming to our shores from the continent of Europe.

THE report of the Lords' Committee on Metropolitan Hospitals, of which we published a digest last week, had been anticipated some months since, and its main conclusions have already been commented on in the columns of THE LANCET. The present Blue-book is only an amended and enlarged form of that previously issued, setting forth the history of amendments and additions, together with some documents of interest, and containing an appendix which furnishes a mass of tables giving the statistics of all the hospitals of the metropolis. These tables must serve for a long time to come, as a reference for the principal facts concerning each hospital, Poor-law infirmary and sick asylum, dispensary, whether free or provident, and nursing institution in London. We need not detain our readers long with the principal conclusions of this inquiry. The voluntary system has been investigated carefully, and there is no doubt that it comes out of the inquiry creditably. The system is conducted economically and yet generously, and the members of the Committee pay a very just and much overdue tribute to the large amount of administrative service and ability which is placed at the disposal of the hospitals of this country. Men of high standing in society and in business give their time and money to these institutions as if they were paid for their services. We heartily endorse this praise. If there is one thing more clearly brought out than another in this investigation it is that, on the whole, the great general hospitals deserve all they receive from the public and, indeed, a great deal more. There are some few faults of administration, but these have been unduly censured and criticised, and the time has now come for more support, in order that the empty wards may be filled with beds for the sick poor and that the hearts of treasurers may be lightened of the load of debt. It is discreditable to think that, with the prospect

of a winter of fog and frost and short employment, so large a proportion of wards must remain untenanted for want of funds. The report appears, or reappears, opportunely at a time when good-hearted and well-to-do men are devising means for abating the miseries of their poorer neighbours. This report will convince them that in increasing their contributions to the great general hospitals of London they are making an investment of charity that will on a large scale avert "death and all the sad variety of pain," while it will go to perfect that art of healing on which their own cure and that of those who are nearest and dearest to them must sooner or later depend.

The Committee has gone fearlessly and fully into the complaints alleged against hospitals and other medical charities—whether complaints of insanitary condition, as in the case of St. Bartholomew's Hospital; of mode of government, as in that of the endowed hospitals generally, and the tendency to the concentration of a too autocratic power in one or two hands; or of the treatment of nurses, as in that of the London Hospital—and the result still is that they prove to be great institutions after all. In the last case the judgment of the Lords' Committee is that the charges against the hospital authorities were "unsubstantiated," and that the difficulties which did occur would have been obviated if the governing board had not allowed their authority to fall too much into the hands of the salaried officers. Nevertheless, the conclusion arrived at is that it is an admirable institution, which confers inestimable benefits on a very large and very poor population. If the profession is dissatisfied with any portion of the report it will be with that which deals with the out-patient department of the metropolitan hospitals, which has been defended chiefly on the grounds of its undoubted uses in medical education. Those who know the tendency of well-to-do persons to enter the open gate of the out-patient department will think that the evil deserved a more severe censure than has been expressed by the Lords' Committee, and that such disapproval might have been expressed without any serious detriment to the cause of medical education. But while not admitting any serious abuse of the out-patient department, the Committee makes suggestions for arrangements (to which we trust hospital authorities will give due attention) for restricting the number of out-patients per diem and for securing inquiry by experienced officials in all doubtful cases. Two valuable proposals are that encouragement should be given to medical practitioners and the officers of dispensaries to use the out-patient department for consultative purposes, and that in such cases the patients should be left under the care of their medical advisers. Not the least instructive part of this fuller edition of the third report is afforded by the Tables of Provident Dispensaries showing the scant rate of remuneration and the small success of these institutions. A better regulated out-patient department on the lines suggested in the report and a trustful system of coöperation between its officers and practitioners and provident institutions outside would tend much to remove the faults of the out-patient department as at present conducted in most hospitals.

The members of the Lords' Committee have evidently had an interesting discussion on the subject of the monopoly of English hospital appointments by the possessors of English

qualifications. They do not allude to the question whether similar monopolies in Scotland are enjoyed by the holders of Scotch qualifications. Lord SANDHURST carried a liberal resolution in favour of the abolition of all territorial restrictions of qualification for hospital appointments against the Earl of ARRAN, who charitably interposed with a proposal to leave things as they are "lest too many of the best of the Scotch and Irish medical men should be attracted to London who should rather be encouraged to stay in their own country." Unfortunately the protest did not succeed, and the unhappy countries of Scotland and Ireland, which have already suffered from their great men being attracted to England, will be in danger of still further calamity on this score!

The Committee expresses no opinion on the fact that by the Public Health (London) Act, 1891, "every inhabitant" suffering from any dangerous infectious disease will henceforth be entitled to free treatment in the hospitals of the Metropolitan Asylums Board. Nurses have their office magnified in this Report, which contains many suggestions for the improvement of their lot.

The recommendation in favour of a Central Board for supervising the hospitals of the metropolis, composed of representatives of all medical charities, and of other medical or charitable bodies, may be regarded as the chief outcome of the labours of the Committee. We have already commented on this proposal, and hope to revert to it at an early opportunity.

## Annotations.

"Ne quid nimis."

### SMALL-POX IN LEICESTER.

It is impossible to foresee the results of the present outbreak of small-pox in Leicester; the number of attacks is not as yet large, hurried demands are being made for vaccination and efforts at isolation are progressing. The disease is, however, spreading, and there are two points in connexion with the measures of prevention on which the town is relying which deserve notice. In the first place, we learn that one family has refused to submit to the Leicester quarantine process. There is no means of enforcing submission to it, and we always anticipated that the real danger to Leicester would lie in a breakdown of this sort. So long as the country was fairly free from small-pox the danger to this unprotected community was trivial, and the so-called Leicester system was never put to any real test. But once let the disease make a little headway, and then such refusals must become numerous, having regard to the miserable accommodation available for carrying it out. We understand that the Royal Commission on Vaccination are about to send Dr. Sidney Coupland, who recently conducted the inquiry for them in the Dewsbury district, to report to them on the present condition of affairs at Leicester. This is in itself a very desirable step. None the less we cannot help thinking that, much as some members of the Commission might deprecate it, the proper course would have been for a representative deputation of the Commission itself to have undertaken this duty. It would only have cost them a few hours to see what provision Leicester has made for its quarantining process, and if they had once gone over the old shed which has long served to safeguard Leicester

the vaunted appliances would have been estimated at their proper worth, and the Commission would have seen that the refusal of respectable people to submit to detention under the conditions that have been available was to be expected as soon as a few families of this class were attacked. The disease has, we are informed, also appeared in a populous lodging-house, but no means exist for "quarantining" all the inmates; and here, again, the system breaks down. The other point is of more serious importance. It is reported that small-pox has spread to some of the scarlet fever patients who are under "isolation" in the same hospital. It is a duty of the sanitary authority to isolate infectious diseases, but it is no true isolation to expose the patients, removed from their homes for the protection of the public, to the infection of an infinitely more horrible disease. So well is the danger of placing small-pox and other infectious diseases on the same site recognised that the practice has almost everywhere been abandoned, and it is well known that for many years past the Local Government Board have refused to sanction any such system. But Leicester people, or rather certain among the authorities of Leicester, have their own views of small-pox, and they appear to be deliberately bringing cases of that disease into the same institution and on to the same site as that which is devoted to the treatment of children unfortunate enough to have scarlet fever, and, as must also sometimes be the case, unfortunate enough to be the offspring of parents who, vaccinated themselves, have been taught to believe that there is no need to give their children the same protection. Leicester may again escape as other towns have done, but the day of reckoning will certainly come, and it may at any time be precipitated by the refusal to submit to an unauthorised detention in an old wooden shed or by deliberately ignoring the now well-known danger of bringing small-pox to the same institution as that within the precincts of which patients suffering from other ailments are detained, and to which they may even be removed against their wills.

### THE INTERNATIONAL MEDICAL CONGRESS OF 1893.

AN Italian correspondent writes: "In the Aula Magna of the University of Rome has just been held a plenary sitting of the 'Comitato Centrale Organizzatore del XI. Congresso Medico-Internazionale,' at which progress was reported and several important steps were taken with a view to the greater success of the meeting and the convenience of its members. This had been preceded by a visit to the Policlinico on the part of the 'Comitato Esecutivo,' consisting of Drs. Baccelli, Durante, Murri, Golzi, Maragliano and others, who went over the completed halls of that magnificent structure, and, as a result of their visit, determined that the various Sections of the Congress shall hold their sittings in these halls next September. The non-completed portions of the Policlinico are being pushed forward with vigour, so as to have the entire edifice ready, if not for use, at least for the inspection and appreciation of the 'Congressisti.' At the banquet which followed the fifth Congress of Italian Medicine the toast of the evening was that of Professor Foà, who drank success to the International Congress of 1893. The Berlin Congress, he said, was especially memorable for Italians, as it was the beginning of a recognition by Europe of what Italy—so great in the remote past—had been achieving in the immediate present, and he expressed the hope, amid the approving cheers of his audience, that in 1893 the Italian wing of the profession would earn yet further recognition in the same honourable sense. It would, he added, be in some measure a crowning of the edifice of national unity if Rome were to become the scene of the 'Instauratio Magna'—of the grand rehabilitation of Italian medicine. In a former communication I spoke

of the apathy betrayed by some of the more provincial schools of Italy as to the importance of the Congress, apathy shown in a tardiness on the part of their *personnel* to signify their willingness to assist at its proceedings. That, I am happy to say, no longer exists; indeed, if any such unworthy feeling still lingers it cannot long survive the hearty sympathy with which King Humbert has thrown himself into the preparations for the Congress, at which, through Dr. Baccelli, he has announced his gracious pleasure to assist, and that he will open the sittings in person. All that now remains to be hoped for is a healthy season—temperate as to heat and exempt from that cholera visitation which the 'weather wise' in epidemiology anticipate."

#### FRIEDENHEIM: A HOME FOR THE DYING.

DEATH must always be accompanied by circumstances of sadness, but the conditions under which dissolution approaches are in some cases peculiarly distressing. In only a few hospitals is accommodation provided for patients for whom all hope of recovery has to be given up. Therefore the humane project started by Miss Davidson some seven years ago, which consisted in founding a Home for the Reception of the Dying, cannot but enlist the sympathy and aid of the benevolent. The Home, situated in the Upper Avenue-road, St. John's Wood, was opened on the 10th inst. by the Duchess of Teck, in company with Princess May and her brother, the Prince Adolphus. The history of the movement was recounted by Dr. Schofield, who has taken great interest in the enterprise, and who entered into some particulars in connexion with the working of the institution. It appears that the patients at the home die on an average in three months, but the care bestowed on them is rewarded in some instances by restoration to health. Except in the paying wards the beds are free, preference being given when a vacancy arises to the most distressing cases. The Home will accommodate forty inmates.

#### SIR JAMES CRICHTON BROWNE ON EDUCATION.

ON the Speech Day at the Reading Grammar School (on the 29th ult.) Lord Coleridge defended Archbishop Laud, who was educated at the school, against the criticisms of Lord Macaulay and enlarged on the advantages of a classical education on the old lines, while Sir James Crichton Browne expressed his interest in the school, as being one that is conducted on sound physiological principles. In the Reading Grammar School, he said, the dual nature of humanity is always held steadily in view; bodily vigour is not sacrificed to the attainment of more intellectual acuteness, and the cult of culture is not altogether subordinated to the worship of the great god Biceps. The head master, Mr. Barnard, has found out how to sail safely in the middle course, avoiding on the one hand the Scylla of bravny and stupid athleticism, and on the other the Charybdis of pale and sickly "punditism"—if such a word might be coined. Hence it has come about that the school is sharing meritoriously in the work that was ascribed at Oxford to the universities a few days ago, and is sending forth boys prepared to be not only men of thought but men of action. It is preparing boys for the universities, for the public services, for the professions, to become good and useful citizens, to make the best use of such faculties as they possess, and to draw from life the happiness that life never fails to yield to all those who have learnt how to live truly. It has long been admitted that one of the first conditions of success in life is to be, as Herbert Spencer has put it, a good animal; but we can now go further than that, and affirm that muscular exercise is essential as a stimulus to brain growth. We have reason to believe that there are tracts of the brain that do not grow properly if the muscles over which they preside are not duly and timeously exercised; and,

as these tracts have mental as well as motor functions, it may be that to curtail muscular activity is to stunt brain evolution and intellectual development. Sir James Crichton Browne insisted that those conducting education should be dominated by a lofty ideal of the schoolmaster's mission, but restrained by a just conception of its limitations. Education is the guidance of growth. We cannot in one generation expand the straitened forehead of the fool and convert it into a spacious dome of thought, unravel the intricately inwoven strands of the brain and knit them up afresh, or alter the whole constitution of the nervous system. What we can do is to train, shelter, foster, nourish, while we extirpate cankers and prune away gadding offshoots. He will be the most successful educator who comprehends alike the possibilities and impossibilities of his craft.

#### THE SPREAD OF SMALL-POX.

WE referred in our last issue to a number of towns where small-pox is now prevalent. The list has already become a much longer one. Small-pox exists to a more or less extent in Bradford, Brimington, Blackburn, Birkenhead, Burton-on-Trent, Carlisle, Chadderton, Daventry, Halifax, Higham-Ferrers, Hull, Leicester, Liverpool, Newport (Mon.); Nottingham, Otley, Rotherham, South Shields, St. Helens, Wakefield, Warrington, Wigan, Willesden, Mansfield and Newark. In some cases it is confined to single families; in others it is much more serious. In Warrington there have now been 243 cases, and 28 fresh cases occurred in the week ending Oct. 29th. The state of affairs in this town has suddenly become so serious that the Local Government Board have sent Mr. T. W. Thompson, one of their medical inspectors, to advise the authorities on the spot. At Otley twenty persons have already been attacked and a hurried attempt at hospital provision is being made. The case of Leicester we deal with separately. On the whole the outlook is highly unsatisfactory. The seasonal activity of small-pox is just commencing, and an amount of neglect as to vaccination prevails which is unparalleled in any of a long series of years before the appointment of the Royal Commission into the subject. The Commission has already been sitting ever since May, 1889, without having made any pronouncement except one, which tended still further to prevent the due administration of the Vaccination Acts, whether by the local or the central authorities concerned.

#### THE BEGINNING OF THE FOG SEASON.

THE meteorological conditions during the past week have been preëminently favourable for the production of fog. A gradual increase of pressure, a distinct lowering of temperature, a persistent envelope of heavy cloud, preceded by wet weather, have all conduced to the formation of those tiny particles of moisture which in a state of suspension in the air give rise to mist; mist in its turn attracts the various impurities existing in the atmosphere of smoky towns, and thus the more objectionable fog is formed. The dangers arising from fog are mostly confined to railway and vehicular traffic, although when it is of unusual density it may affect the safety of foot passengers as well. Precautionary measures have been taken this year at the London Docks, where chain fences have been erected on the quays and the edges of the platforms have been painted white. The character of the familiar reddish-brown fog of London is very distinct. Travellers from the suburbs must frequently notice the difference of smell between the fog, or rather mist, enveloping their homes and that which envelops the city. Suburban mist is characterised by a smell which recalls the odour of crude carbonic acid and is probably derived from the decomposition of autumnal leaves. But the moment the traveller arrives in town he observes at once that

the impression conveyed to the nose is exactly that experienced when a fire is first lighted. The smell of London fog is, in fact, that of wood burning. This naturally suggests that if the lighting of fires could be dispensed with much of the evil might be mitigated. Or if coal fires could be allowed to burn slowly overnight, so as to dispense with morning lighting, the nuisance might—to some extent, at any rate—be avoided. Although all are agreed that fogs and mist constitute a pest which must be got rid of, there remains one compensating advantage which has often been overlooked. It is reasonable to suppose that a fog effects a partial purification of the atmosphere. This is borne out by the fact that when a fog subsides the deposit contains the carbon, sulphur, organic bases and other injurious and irritating particles which formerly existed in a state of suspension in the atmosphere. Just as water is freed from objectionable suspended matter by the addition of an impalpable powder, or a mixture which gives rise to a fine precipitate, so probably is the air deprived of suspended impurities by the subsidence of the moisture particles in which the impurities become entangled. It is a matter of common observation that the air is remarkably clear after the subsidence of fog or mist. Wind or rain are, however, equally effective and much more agreeable agents in accomplishing this purification. If we cannot get rid of mists while we are beset with the peculiar conditions which characterise the climate of this country, we can at least make an attempt to prevent the emission of those particles into the air which convert that mist into the intolerable and irritating vapour ever known and remembered as London fog.

#### A LABOUR COLONY FOR EPILEPTICS.

HOSPITALS for the sick in mind and body, homes for the incurable, for the dying even, school prisons for the cure of moral errors, and many like ventures of humane zeal attest the earnestness and often also the wisdom of Christian charity. Both qualities are apparent in an undertaking which owes its origin to German enterprise, and which, as was announced in THE LANCET on Aug. 6th and Aug. 13th, has already found an extension in this country in the Home for Epileptics at Godalming, which was recently opened by the Duchess of Albany. This colony for epileptics was founded some twenty-seven years ago near Bielefeld in Westphalia, and was lately described in the *Contemporary Review*. Its germ, the labour home or Bethel, has during this period undergone very extensive developmental changes. Designed in the first instance for male adults, it opened its doors at a later stage to women and children also, with the natural result that lack of space soon rendered it necessary to open other similar establishments. A portion of the adjoining Teutoburgian forest was acquired at small cost. The cheap and willing labour supplied by the male inmates after a time reduced to a state of comparative cultivation what was formerly mere waste land, and a thriving village sprang up as the result of their exertions. Here by degrees an increasing number of stricken people of all ages have gathered and are now accommodated in cottage homesteads according to their relative ages, condition in life and the stage of their malady. Agriculture has from the first proved to be the most successful form of work in which the men of the colony have been engaged, and the fruits of their tillage are in wide request. Handicrafts are practised also, but these, owing to the cost of instruction and other causes, have not been found equally profitable. One great difficulty has been to secure suitable employment for the women. In the instruction of the children a greater degree of success has been attained, and it is noteworthy that none of those inhabiting the Bethel homes have lost their reason.

Steady work forms the main feature in the system pursued in the colony, and every care is taken by this means—by maintaining cheerful associations, by wholesome nutrition, and by avoiding causes of mental irritation—to guard and strengthen the nervous health of its inhabitants. As yet it is not self-supporting. This fact, however, does not disconcert the managing committee, whose aim is rather to make it first a philanthropic and then a commercial success. The chief difficulty connected with the working of such an experiment as this consists in the moral contagion almost inevitably associated with nervous disease. This does not seem to have proved itself an insuperable obstacle in the case before us, and we are thus encouraged to hope that the Westphalian system may on further trial be found worthy of more general adoption.

#### OPENING OF SCHOOL-BOARD PLAYGROUNDS.

IT was not to be expected that the recent action of the London School Board, in throwing open to the children of adjacent neighbourhoods a number of playgrounds under its management, should pass entirely without censure on the score of economy. We are not therefore surprised to learn that the expenditure thus incurred was disallowed by the officiating auditor. Happily for the children of the metropolis, however, this decision was not approved by the Local Government authorities, and there is a prospect that the access thus generously afforded by the Board to the means of recreation at its disposal will constitute a permanent source of pleasure and of health to those whom it was designed to benefit. We can only trust that it will be found convenient to extend still further the scope of this useful arrangement and to open with a like purpose those playgrounds which as yet remain closed to others than children attending the schools. We need not enter into details as to the obvious benefits thus conferred upon the health of city children. Their most prevalent malady—anæmia, with its associated weaknesses of constitution in which are sown and bred the germs of numerous and serious ailments—knows no remedies equal to fresh air and a sufficient dietary. Money may not be available for the latter, however plain it be; home is commonly but a name for crowded uncleanness. In such a case it is very desirable even to afford the opportunity for free action of limbs and lungs in an atmosphere which is at least the purest obtainable.

#### THE PHYSIOLOGY OF THE IRIS.

SOME years ago Dr. Brown-Séquard startled physiologists by stating that the iris responded to the direct action of light, and demonstrated the fact by dividing the eyes of eels and frogs into a posterior and an anterior half, and directing a ray of light upon the iris. The contraction of the sphincter pupillæ under these circumstances showed that at all events the act was not of a reflex nature through the retina, but it was possible that ganglionic cells might be distributed in the tissue of the iris, which might be sensitive to light and liberate motor impulses in obedience to that stimulus. Steinach has recently investigated the subject, and by a series of careful observations has arrived at the conclusion that the contraction of the iris when detached from the retina is due to the direct action of light upon its structure. In frogs kept for some time in a dark cool room, and especially in the brown grass frog (*rana temporaria*) and also in other amphibia and in many fishes, the phenomena may be easily demonstrated even in the isolated iris. He found that no effect was produced by illuminating the peripheral zone of the iris (ciliary region); but it was necessary that the light should fall on the pupillary margin, of which, if only a segment be acted upon, contraction occurs. The contraction still happened when the nervous apparatus of the iris was excluded by the

action of atropine. Steinach demonstrates that the contraction is not due to the influence of the chromatophores and entertains no doubt that it is really the muscular fibres of the sphincter that are acted on directly. He has made numerous examinations of these, and finds that in amphibia and fishes they are strongly pigmented. In eyes that have been exposed to the light they are short, thick, and not very well defined; whilst in animals that have been kept in the dark they are slender and sharply contoured. He regards the presence of pigment in these muscular fibres as the determining cause of their sensibility to light. The several rays of the spectrum are not all of equal power in causing contraction in the isolated iris. The red rays up to the line C are comparatively ineffective, but the power increases up to the line F, where it reaches its maximum, and from this point it gradually diminishes. In a comment upon this paper Langendorff remarks that other muscle cells besides those of the sphincter pupillæ possess pigment granules in their interior—as, for example, those of the tensor choroidæ in mammals.

#### MEDICAL MAYORS.

THE following members of the medical profession have been elected to the mayoralty for the ensuing year in the under-mentioned towns. We shall be glad to receive an intimation of any omission which may have occurred in the subjoined list:—Bacup, Alderman W. J. Clegg, M.D., M.R.C.P. Edin.; Brighton, Alderman Joseph Ewart, M.D. St. And., F.R.C.P. Lond.; Chipping Norton, George Wright Hutchison, M.D. Aberdeen, M.R.C.P. Edin.; Crewe, William Hodgson, L.F.P.S. Glas., L.K.Q.C.P. Irel.; Hastings, A. R. Croucher, M.D. St. And., M.R.C.S.; Louth, Palemon Best, M.B. Lond., M.R.C.S.; Lymington, W. R. Hill, M.D. Edin., M.R.C.S., J.P.; Montgomery, N.W., Fairless-Humphreys, M.R.C.S.; Ruthin, J. M. Hughes, M.B., M.S.; Saffron Walden, John Parkinson Atkinson, M.D. Glas., L.R.C.P. Lond., L.R.C.S. Edin.; St. Ives, Cornwall, J. M. Nicholls, L.R.C.P. Lond., M.R.C.S.

#### THE ACCIDENT TO A SCOTCH EXPRESS.

THE lamentable accident which happened to the Scotch express near Thirsk on the morning of Wednesday, the 2nd inst., has directed public attention once more to the subject of the overwork of railway servants and the risks not only to the men themselves, but also to the public, which such overwork involves. The matter is one to which we have on many occasions referred. The evidence furnished by Parliamentary reports, upon which our comments have chiefly been based, has been much stronger than that furnished by the facts of the present case, but, naturally enough, the public mind receives from a disaster like that which occurred at Thirsk an impression which could not be communicated by even the fullest and most significant statistics. The very frank statement made by the signalman will very properly do much to attract public sympathy to him in his most painful position. That sentiment will be quite independent of any question of apportioning blame that may have hereafter to be considered, and we are very far from wishing to anticipate the verdict of a qualified tribunal that will doubtless be called upon to consider the case. But one thing seems to be clear, even from the fragmentary statements already made public—namely, that whatever improvements it may be possible to introduce into the conditions of the employment of signalmen, a further protection for the travelling public must be sought in the general adoption of an efficient system of interlocking signals. The effects of overwork may arise, even where the limits of a man's regular employment are most carefully laid down, in consequence of accidents which break in upon the repose of his leisure time. Moreover, even when there is no overwork or

undue strain of any kind to cause special danger, there is the danger that is always present of a sudden attack of illness, which makes human agency a necessarily untrustworthy instrument with which to work. That a solitary man shut up in his signal-box should have the power by a mistake to bring on a catastrophe like the collision of two trains is of itself a standing and startling peril, and one which can be and should be dealt with at once. The singular immunity from serious accidents which we enjoy in the ordinary course of railway travelling has led the authorities and the public also to look with too great complacency upon the slow progress which the improvement of our system of railway working makes and the long interval by which the ordinary practice is separated from the best knowledge of the hour. It is to be hoped that among the lessons of the calamity which we are now deploring this one will not be lost to the public mind and conscience, and that those especially who are responsible for railway administration, whether in the way of the actual work or the official supervision, will bestir themselves to bring about a system under which the evil consequences of those mishaps that must happen under any imaginable system may be minimised and the public safety secured not only by the diligence and skill of those who control the mechanism of our railways, but by the foresight of those who design it and in designing have an eye not less to the possibilities of its breakdown than to its smooth working.

#### PARALYSIS FROM ARSENIC POISONING.

TWO cases of this nature recorded by Erlicki and Rybalkin are referred to in a recent number of the *Neurologisches Centralblatt*. The course of the affection was similar in the two cases. It commenced with irritability of the gastrointestinal tract, general weakness, paresis of the extremities with atrophy, contractures and changes in electrical irritability and sensory changes. In one case also there was some mental disturbance. One patient improved after two years; the other died of phthisis after the lapse of a year. There was found degeneration in the peripheral nerves, together with changes in the anterior grey horns, especially in the lumbar and cervical enlargements. The ganglion cells were reduced in number and those that remained were altered in shape and size, while the protoplasm was in part replaced by pigment. The processes of the nerve cells were deficient in part, and some of the cells contained vacuoles. The nerve fibres also in the anterior horns were reduced in number. Professors Erlicki and Rybalkin regard the alterations in the cells in such conditions as being due not so much to the direct action of the poison as to the mechanical alterations in the circulation and to physiological and chemical peculiarities in the blood.

#### THE PREVENTION OF CRUELTY TO CHILDREN.

THE National Society for the Prevention of Cruelty to Children is to be congratulated on the continued success of its efforts. According to its latest published report, the total number of cases investigated during the year 1891-92 was 8324. Of these, 7291 proved to be genuine, and of 1115 in which a prosecution was instituted, 1042 resulted in conviction and punishment. These facts bear out the truth of remarks for which we are indebted to the experience and candour of a well-known judge, who tells us that he cannot recall a case of prosecution by the Society which has not been justifiable, or more than one which has not been successful. Surely no stronger terms of commendation could better assure the Society's reputation for judicial fairness in the conduct of its work. Another proof to the same effect is found in the excellent understanding which exists between its agents and the police officials. We are pleased to learn from the report that wherever the law

has been applied with due firmness to the repression of cruelty this vice in its severer forms of savagery has undergone marked diminution. Notice is taken of the important fact that in a large proportion—this year 3809—of the cases investigated the children have been insured, and we congratulate the Society on its vigilance in promoting legislative activity both with respect to a form of providence which is open to abuse, and to the disposal of nurse-children. Finally, we trust that its agents will prosecute with due energy their inquiries as to a dangerous custom prevalent in some quarters—namely, that of drugging young children with laudanum. This familiar practice of Eastern motherhood cannot safely hold a place in English domestic life. The Society's income shows a satisfactory increase which we trust will be maintained during the current year, and for the employment of which, as we have shown, deserving objects can still be too easily found.

#### CEREBRAL ABSCESS.

IN a recent number of the *Berliner Klinische Wochenschrift* a brief abstract of a case by Zeller, read before a meeting of surgeons in Berlin, is given. The patient became ill in the middle of January with symptoms of influenza. A phlegmonous process followed in the right orbit. This was laid open and the pus evacuated. But soon after the patient began to suffer from pain in the head and vomiting. There was no cranial nerve paralysis, but both discs were injected, and on the left side blurring of the edge was present. On account of the absence of any progressive tendency in the symptoms and the localisation of the painful area to the right forehead close to the middle line the diagnosis of abscess was preferred to that of meningitis. Professor Sonnenburg operated, first of all laying open the old abscess cavity, but finding nothing except a small defect in the roof of the orbit. He then incised the right side of the forehead and trephined the frontal bone near the middle line on the right side. The dura mater did not pulsate, but, on probing, pus was found in the right frontal lobe anteriorly, and finally sixty cubic centimetres were evacuated. The pulsation returned at once and materially aided in the evacuation of the abscess cavity. The drainage-tube was gradually shortened and finally removed, and only a small granulating surface remained. All the symptoms had subsided, and in a later note it is added that the patient had been discharged from the hospital completely cured.

#### THE POSTMAN'S KNOCK.

IT is easy to see that a correspondent who expresses himself with some emphasis respecting the familiar postman's knock, notwithstanding that he veils his protest under a covering of quaint humour, has given utterance to a genuine sense of injury. His appeals to the busy, the studious, the nervous, the irritated and the sick are not wanting in a kind of pathos. Neither can it be said that they are without some rational foundation. What Londoner has not occasionally been startled by the sharp, loud and sudden double knock when it descends upon the entrance-door of our dwellings after dark and rings through the stillness of the hall or passage beyond? There are times, no doubt, when the sound is welcome. We are well, at leisure, our nerves unshaken, our expectations not unpleasant, and the well-known sound affects us neither much nor disagreeably. There are likewise other and opposite conditions. Weariness and illness have perhaps found a brief respite in slumber. Or it may happen that the mind is for the moment poised at a crisis of thought or strains in effort. At such a time we bless (not sincerely) the slightest trifle of distraction; how much more this loud and instant reverberation from the official outer world. The ancient preacher would no doubt have told us that there was a time to refrain from knocking, yet established rule knows only its

own noisy custom. Relief must be sought by personal exertion. A decided step in this direction would consist in the total abolition of door-knockers, and certainly a bell, whether of mechanical or electric origin, possesses in this connexion distinct advantages. Where no such reform is allowable, muffling provides a partial remedy almost too familiar for mention. Again, in the extreme case, such as sleepless irritability, where no avoidable sounds can be tolerated, householders might easily prohibit by a warning placard the use of either bell or knocker. The postal summons may be indispensable, but we see no reason why it should not be tempered by one or other such means as we have here noted.

#### "REMOVAL OF TUMOUR FROM THE SPINAL CANAL."

WITH regard to the case of spinal tumour referred to last week, we understand that Dr. Ferrier and Mr. Watson Cheyne are preparing full notes of the case for early publication in the columns of THE LANCET. The tumour was intra-dural, had been growing probably for eight years, was situated opposite the seventh to the tenth dorsal laminae, and was easily and quickly removed without any injury to the cord or nerves. The cause of the patient's death is by no means clear, the main symptom afterwards being irregularity in the heart's action, which began when the position of the patient was changed prior to the commencement of the operation.

#### LONDON BOARD SCHOOLS.

THE Lambeth Vestry has recently taken out a summons against the London School Board for having allowed the lavatories to be in a foul state so as to be dangerous to health. At the request of the School Board the magistrate granted an adjournment on the ground that the work ordered by the officer of health was being carried out. It cannot be denied that the fact that the Vestry have taken out a summons, and that the necessity of the work is not disputed, reflect on the management of the Board. With any reasonable supervision this would have been impossible. Seeing that parents are required by law to send their children to school, every care should be taken to ensure that these schools are free from dangers to health; it is obviously the duty of the Board not to wait for the compulsory action of the sanitary authorities, but to initiate at once any improvements that may be necessary. It would be interesting to know what machinery the Board has at its disposal for performing this very necessary duty, and we trust this question will be asked at an early meeting of the Board.

#### ARREST OF HÆMORRHAGE AFTER TOOTH EXTRACTION BY HOT WATER.

DR. JULIUS SCHEFF, jun., of Vienna, according to the current number of *Ash's Quarterly Circular*, recommends strongly the use of hot water for arresting hæmorrhage after tooth extraction. "We are accustomed," he writes, "to stop hæmorrhage by the method that has been used for generations—viz., by the direct application of cold water to the wound. Practitioners started with the idea that heat caused expansion of, and induced increased bleeding from, the vessels; but, on the other hand, cold caused contraction. In an ordinary case of extraction hæmorrhage from the arteria dentalis, or from the gums and periosteum, soon ceases; but it frequently happens, even when the patient does not suffer from hæmophilia, that there is difficulty in arresting the flow of blood." Dr. Scheff mentions three cases occurring in his practice in each of which there was a history of profuse hæmorrhage after extractions. "I allowed one patient," he says, "to take a great quantity of cold water, and yet there appeared not the slightest diminution in the bleeding. I then took a glass

syringe and continuously applied hot water in drops to the wound, from which the blood previously trickled without cessation. After a few seconds the bleeding diminished, a coagulum was formed, and the bleeding finally ceased. With the second patient I used hot water at once, and the flow of blood was arrested. In the third case the wound had been bleeding freely for a long time; I plugged the alveolus with iodoform gauze, and on removing the plug the wound bled afresh. I then employed hot water; the hæmorrhage ceased and did not recur." Dr. Scheff applies the hot water by means of a syringe, injecting it by drops into the socket of the tooth. "The arrest of hæmorrhage in surgical operations by the application of heat is a recognised resource, and it would therefore seem that this principle might with advantage be applied in cases of tooth extraction, especially as the mouth is able to bear a very high temperature without inconvenience. In fact, water so hot that it causes pain when the finger is inserted in it will in many cases be tolerated in the mouth.

#### VACCINATION AND SMALL-POX.

It is difficult for the majority of people living at the present time to appreciate the injury done by small-pox before vaccination was generally adopted, but the opposition shown to vaccination in certain localities threatens to make small-pox in our time as terrible a calamity to the community as it was in the early part of the century. Warrington is now visited by this disease, and on Saturday an inquest was held upon the body of a girl who had died from small-pox and who had had no medical attendance. The necessity for the jury to view the body led the coroner to arrange for this to be done at a safe distance, and when it was afterwards stated that one of the jurymen had entered the place where the body was laid out, the coroner said the particular jurymen would be excused from serving. Probably these precautions were necessary, but we may well contrast this possible risk with the safety with which revaccinated nurses in small-pox hospitals attend upon the sick. But it is not matter for surprise that ignorant persons should be led to possess exaggerated views of the risks of vaccination, and should fail to appreciate the nature of small-pox. We have before us an advertisement of a lecture given this week in the Public Hall, Rochdale. The lecture is announced by the Rochdale Anti-compulsory Vaccination Society. The advertisement contains the notice that the lecture will be illustrated with limelight views, and that "as some of the pictures are very painful, sensitive persons are requested not to attend." While all these efforts are being made to discredit vaccination, we would suggest to medical officers of health the necessity of seriously endeavouring to combat the prejudices of the many who have no opportunity of forming any correct idea of the dangers to which unvaccinated persons are exposed.

#### THE INVESTIGATION OF INDIAN DISEASES.

WE gather from the Indian newspapers that a conference will probably be held at Calcutta during the present cold weather with the view of settling where a bacteriological observatory is to be established in India. It is said that the bacteriological observations at Lahore and Poona have not been a success owing to the climatic conditions of those places. There is no reason, of course, why the work at these laboratories should be confined to any particular branch of pathology or hygiene, but it is time that India should apply all the latest methods of modern scientific research to the investigation of disease-causes. The diseases that prevail in India not only cause a great loss of life there every year, but as regards one of them at any rate—namely, cholera—India is regarded by many authorities as the birthplace and starting-point whence epidemics of that disease derive

their origin and spread to other and distant countries. It is consequently only right and proper that the imperial power which rules India should accept the responsibility of its position, and spare no pains to provide the means and all modern appliances for instituting a scientific inquiry into its exact nature, origin, causes and modes of spreading. There are other diseases also, enteric fever for example, into the exact nature and causes of which further information is urgently needed. But, as we have said, there are many subjects calling for further investigation in India, the study of which would not lack practical interest and application, and the Government of India could not fail to reap advantage from such investigations. We should like to see something like an institute of preventive medicine organised and established in India, with its bacteriological laboratories in connexion with a public health department distributed over India consisting of different local bodies at various stations, each one made up of a medical officer and an engineer officer of the public works department, specially trained to the work. The principal medical officer at any station might then refer to them on the occurrence of any local outbreak of disease, and they should at once proceed to undertake its investigation, with the aid of, and in connexion with, the Institute of Preventive Medicine, to which all matters requiring bacteriological or special methods of investigation should be referred for report. The Government possesses in Surgeon-Major D. D. Cunningham an officer well adapted to act as the directing head of such an institute, who should work in connexion with a staff of medical officers, a sanitary engineer officer and a chemical examiner attached to the institute. As regards the details of the scheme, however, these could be best settled in India.

#### "INFANTILE RESPIRATORY SPASM."

IN a paper recently read before the Edinburgh Medico-Chirurgical Society Dr. John Thomson gave a short account of five cases that had come under his observation in which this curious and interesting condition had existed. It is also known as congenital laryngeal stridor, or infantile laryngeal spasm, and Dr. Gee has described a similar, although somewhat different, condition under the term "respiratory croaking." Of Dr. Thomson's five cases, three were boys and two were girls, whereas in all previously recorded instances where the sex is mentioned it seems to have been confined to girls, and the condition is often said to occur only in female children. As regards family history and general health, there was nothing of very great significance, except that in four of the cases more or less indigestion was present. In none of the patients was rickets apparent when the children were first seen, but it appeared later in those longest observed. There was no sign of congenital syphilis in any of the cases, and intellectual development seemed perfectly good. The onset of the stridor was noticed in three instances immediately after birth, but in one infant it was not observed until a week, and in the other a fortnight, later. As regards the course of the malady, Dr. Thomson says that in severe cases the stridor goes on increasing in loudness during the first two or three months and then tends to subside spontaneously, and as improvement goes on the intervals become longer and the sound less loud, that accompanying inspiration, the crowing sound, disappearing first, while the croaking may still be present at times. After the stridor has ceased to be heard under ordinary conditions it may reappear if the child is specially excited or angry; when the stridor is present inspiration begins with a croaking noise and ends in a high-pitched crow. When the breathing is quiet the latter does not occur. Expiration is accompanied by a short croak when the stridor is loud, but at other times it is noiseless. As regards other symptoms, the indrawing of the chest wall and the episternal notch were well marked in four of the cases, but the

also nasi did not move with respiration, and there was a striking absence of distress or cyanosis. Variations in the intensity of the sounds were not uncommon, and there were occasional intermissions, even when the condition was most constant and severe. The sounds were notably intensified by mental perturbation, more so, apparently, when the child was excited and apprehensive than when actually crying. Sleep seems to have no constant effect on the condition, and it does not cease when the tongue is depressed, nor even when the nostrils are closed, and when the child is taking the breast there is still sufficient air entering the nostrils to cause loud stridor. The effect of the ailment on the general health is not great, and the most effective treatment apparently is by regulation of the diet and other general precautions. Dr. Thomson regards the condition as due to spasmodic muscular contraction, the cause of this being some central disturbance of function, and he considers it closely analogous in nature and etiology to ordinary speech stammering, both being the result of defect in the proper coördinating mechanism.

#### MYOPIA IN CANTON GENEVA.

DR. E. SULZER, *privat-docent* in ophthalmology in the University of Geneva, has memorialised the Minister of Public Instruction for permission to make systematic investigation into the proportion of the myopic youth, male and female, attending the schools in the canton, and having obtained the Minister's sanction has for some time been at work on the materials of an official report. This document, Dr. Sulzer announces, will have a twofold reference—one for the medical profession and another and more practical one for those engaged in teaching. As regards the prevalence of myopia in Switzerland, France and Germany, Dr. Sulzer has already instituted a statistical comparison, from which it would appear that this affection is far less common in the former of these countries than in either of the two latter. In Germany and France, indeed, but particularly in Germany, the subject has for years engaged the serious attention of the Government, while in Great Britain the malady, if not so pronounced, is at least common enough to justify official investigation such as that undertaken by Dr. Sulzer. "Over-pressure" may assume other forms besides those arising from brain fag; and myopia is one of them.

#### NURSES FOR CHOLERA.

WE observe with much satisfaction that active steps are being taken to prepare for a possible visitation of cholera next year. One of the greatest difficulties which will have to be met is to find a sufficient supply of competent nurses to take charge of the sick in any locality in which the disease may appear. The duty of making the necessary provision will be imposed on sanitary authorities, but we anticipate that it will be no easy task to meet the demands which will be made upon them. The forethought of Her Royal Highness Princess Christian in bringing together representatives of the Royal British Nurses' Association and the Society of Medical Officers of Health is therefore much to be commended. On Monday the late Lord Mayor, Sir David Evans, presided at the Mansion House over a meeting of this Association and the Council of the Society of Medical Officers of Health, at which Her Royal Highness was present. The meeting was well attended, among those present being Sir Joseph Fayrer, Sir Dyce Duckworth, Dr. Thorne Thorne, C.B., Dr. Bezly Thorne, Mr. Shirley Murphy (President of the Society), Dr. Heron, Dr. Armstrong and Dr. Sedgwick Saunders. Dr. Thorne Thorne explained the duties which would devolve upon sanitary authorities, and Dr. Bezly Thorne gave an account of the steps which it was proposed should be taken by the Nurses' Association. It was arranged that a roll of nurses should be at once opened which should con-

tain the names of all who were willing to serve, so that sanitary authorities should have immediately at their disposal a staff of trained women ready to undertake this important duty. We trust that this invitation will meet with a cordial response, and that many nurses will be willing to render this public service. The Lord Mayor undertook to communicate with the mayors and provosts of other towns, and every effort will be made by medical officers of health to make this movement known throughout all parts of the country. We sincerely wish it every success. The public has every reason to be grateful to her Royal Highness for this timely and valuable suggestion.

#### THE SEMMELWEIS INTERNATIONAL MEMORIAL.

THE Executive Committee appointed on the 24th ult. have issued an appeal to the medical profession in favour of the above object. The hon. secretary has written to us to express the cordial thanks of the members present for the support rendered by THE LANCET to the movement. We shall be glad to find, when the first list of subscriptions comes to be announced, that the appeal has been widely responded to. It may be observed that the maximum subscription to the fund has been limited to one guinea, which should be forwarded to the secretary, Dr. C. J. Cullingworth, as early as possible.

#### CONJUNCTIVITIS AT CARLISLE.

THE number of cases of a rather severe form of conjunctivitis which have appeared in Carlisle during the last fortnight has been the subject of comment amongst local medical practitioners. The inflammation has been accompanied with redness and heat of the skin of the eyelids, as well as swelling and deep injection of the mucous surfaces of the eye. There has been observed in some cases hæmorrhagic patches round the cornea. The eyes have not been attacked simultaneously, usually a day or two intervening. Pain in the forehead and temples has been severe. So far no grave mischief has been associated with the conjunctivitis and the cases have convalesced rapidly.

#### DIPHTHERIA AND THE METROPOLITAN ASYLUMS BOARD.

MR. LITTLE, in his last letter to *The Times*, makes a point of the occurrence of diphtheria amongst children convalescent from scarlet fever in the hospitals of the Board. The complication of scarlet fever by diphtheria certainly has occurred in the hospitals to an extent which has caused anxiety to the Managers and their able medical officers. But it is a complication not confined to cases in these hospitals, and we gather from the last report of the statistical committee of the Board that its occurrence has been of late less, rather than more, frequent. Thus in the Western Hospital fourteen cases of diphtheria occurred in scarlet fever cases in 1891, as against thirty-three cases in 1890. In the South-Western Hospital only one such case occurred. In the South-Eastern Hospital no mention is made in the report of the medical officer of such a complication. In the Northern Hospital eleven cases occurred last year. While this complication, graver and more fatal than any other of scarlet fever, must be severely watched and combated, it is only fair to admit that the two diseases have some subtle points in common and some subtle relation to each other which pathologists are only beginning to realise and to study. It frequently happens, according to Dr. Gayton of the North-Western Fever Hospital, "that a case certified as diphtheria and having the well-marked throat symptoms connected with the disease was found some days after admission to be desquamating. In other words, the case was one of scarlet fever plus diphtheria, a natural result ensuing—the infection of others in the ward." It seems very important first that all

such doubtful cases should be placed in a separate ward, as Dr. Gayton suggests, till their real nature is made clear, and, secondly, that minute inquiries should be made of the history of the patient *before admission*, and the result of such inquiries communicated to the local sanitary authority.

#### MICROBES IN WATER.

IN an experimental study upon the microbes of water with application to the sanitary hygiene of the town of Lyons Dr. Victor Despeignes (*Étude Expérimentale sur les Microbes des Eaux avec Applications à l'Hygiène Sanitaire de la Ville de Lyon*) goes very carefully into the whole question of primary infection of river water, of filtration and of secondary contamination. He records the results of a very large number of observations and experiments and comes to the following general conclusions: that the water distributed to the inhabitants of Lyons, although filtered under good conditions, possesses, when it arrives at the distributing taps, bacilli so numerous that they constitute an appreciable danger to the public health. The wells of Lyons, all excavated in extremely permeable soil, and therefore very easily contaminated under the influence of variations in the level of the ground water by the neighbourhood of sewers and privies, should be absolutely forbidden. Only in a very few cases can they provide water equal to that supplied from the Rhone, and being subject to numerous modes of infection they are sources of very great danger, as is evidenced by the epidemics which are so frequently attributed, and even traced, to their presence. The waters of the springs of Lyons are not absolutely pure; they become easily contaminated by means of "fissures" and "faults," and putting aside all question of quantity they cannot be looked upon as sufficiently sterile for the authorities to think of utilising them for drinking purposes. The paper is a good practical treatise and affords evidence of the valuable work that is being done in connexion with water-supplies.

#### EXTIRPATION OF THE LARYNX.

ON Oct. 19th Dr. M. Grossmann read a paper before the Vienna Medical Society on Death after Extirpation of the Larynx (*Wiener Medicinische Wochenschrift*, No. 43, 1892). He considered briefly the history of laryngology, dwelling especially on the researches of Galen, who showed that when the recurrent nerves were cut through on both sides the voice was lost. Experience had shown that cases in which the larynx had been totally or even partially extirpated often ran a peculiar but characteristic course, ending in death. From two to five days after the operation, although apparently the wound was healing well, a remarkable change was noticed in the pulse; generally the number of beats per minute fell from 80 to 40, or even 20, whilst in another class of cases the number rose to 160. Oedema of the lungs then set in, followed by "paralysis of the heart" and death. Professor Koch had maintained that after extirpation of the larynx these symptoms were due to the division of the depressor nerves, which ran an abnormal course, and thus the accelerators were unopposed; and one of his pupils had demonstrated that the superior cardiac branch of the sympathetic often arose from the superior laryngeal nerve. But Dr. Grossmann thought that the following arguments told against Dr. Koch's theory: (1) The depressor nerve is centripetal; (2) the vagi remain intact; (3) the symptoms in question often arise when the operation has only been one-sided; (4) there is always an interval of some time between the performance of the operation and the development of the symptoms. Dr. Grossmann considers that these serious symptoms are not caused merely by the division of the nerves, but by changes occurring during the healing of the wounds. In order to test these theories Dr. Grossmann performed a series of experiments upon animals.

He first ascertained that if the laryngeal nerves were simply divided very little change was noticed in the heart and circulation, but if the trunk of the superior laryngeal nerve was irritated two phenomena presented themselves—namely, rise of blood pressure and slowing of the pulse. As regards the condition of pressure in the left auricle and ventricle, irritation of the laryngeal nerve (carefully isolated) did not always cause a rise of pressure; very frequently the reverse condition ensued. Increased pressure in the left auricle caused congestion of the pulmonary circulation, and thus are explained the symptoms which Professor von Basch first drew attention to—oedema of the lungs and defective aeration of the blood: Phrenographic curves obtained by Dr. Grossmann in his experiments showed an increase in volume of the lungs even when both vagi were divided. In considering these experiments it must be remembered that an increase of blood pressure does not necessarily denote increase of work on the part of the heart; there may be other factors at work which paralyse the unfavourable influences acting on the heart, and this is probably the explanation of the fact that these symptoms do not always occur after extirpation of the larynx. From his researches, therefore, Dr. Grossmann deduces the conclusion already stated—namely, that the cardiac symptoms and ultimate failure are produced not by division of the laryngeal nerves, but by the irritation of the trunks of the nerves, produced by changes (not precisely determined) proceeding in the wound.

#### TRANSFUSION OF BLOOD IN POISONING BY COAL GAS.

ABOUT twenty years ago transfusion of blood was warmly recommended, especially in certain cases of anæmia and after inhalation of coal gas. The treatment then fell gradually into some disrepute, but is still occasionally recommended as offering a good chance of recovery. Of fifteen cases of inhalation of gas, collected by Landois in the year 1874, six terminated favourably, eight ended fatally, and one case remained doubtful after the transfusion. Some authors also recommend transfusion of a solution of common salt in place of blood, while others dispute the permanent effect of the salt and give the preference to transfusion of blood. Dr. Siegmund Löwenthal publishes in the *Medicinisches Centralblatt* a case from Professor Drasche's wards in the Imperial General Hospital at Vienna. A medical man, eighty years old, had inhaled coal gas during a whole night and was found the next morning in a state of coma, evidently due to poisoning by carbonic oxide. Attempts at resuscitation by artificial respiration and by applying galvanism to the phrenic nerve were unsuccessful, and the patient was then brought to the hospital. Here camphorated ether was first injected, and then a hypodermic injection of a solution of common salt was made into the abdominal and gluteal regions, but without any good result. Dr. Jahoda then ordered a transfusion of blood taken from the son of the patient, but no improvement was visible. Coma continued, and in two days the patient died. At the post-mortem examination cerebral atrophy was found, with softening centres in both lenticular nuclei and also on the anterior peduncle of the internal capsule. Numerous lobular and puriform centres of a pneumonic character were observed in the lungs, and the kidneys were atrophied. According to the cases published by Klebs, Simon, Ziemsson and Pölchen the appearance of the brain described by Dr. Löwenthal is characteristic of death from the inhalation of coal gas. The centres of softening in the large cerebral ganglia, chiefly observed in the middle and inner portions of the lenticular nucleus, are due to fatty degeneration of the afferent vessels and the consequent considerable contraction of their lumen. It is noteworthy that in the case related above the transfusion of blood did not meet with even temporary success. The pro-

able reason why all attempts at resuscitation failed was the patient's advanced age and the consequent want of elasticity in the bloodvessels. Dr. Löwenthal believes that the transfusion of blood in any case cannot have much effect in counteracting the poison of coal gas, as it does not change a sufficient quantity of the co-hæmoglobin into hæmoglobin itself, and the quantity of poison removed by the mechanical process is too small to be of much service. Transfusion of a solution of common salt is preferable, which, though increasing the quantity of liquids in the organism, also causes a considerable increase in the quantity of urine secreted. A necessary condition for a successful issue is a healthy state of the brain.

#### THE MEDICAL OFFICERSHIP OF THE GLASGOW POST-OFFICE.

WE understand that Dr. Dougan has been appointed to this post at a salary of £800 a year. The number of applicants for the appointment was very large, and included gentlemen from all parts of the United Kingdom. Dr. Dougan was lately medical officer of the Argyllshire District Asylum.

#### MEASUREMENT OF INTRA-TRACHEAL PRESSURE.

BY introducing a manometer tube into the trachea in patients who had had tracheotomy performed Dr. Aron has been able to note the intra-tracheal pressure under various circumstances. He found that inspiration is frequently divided into two portions, but that expiration is always continuous. In quiet breathing the manometer marked in inspiration from - 2.08 millimetres to - 6.65 millimetres of mercury; in expiration from + 1.23 millimetres to + 6.29 millimetres. In coughing the inspiration pressure was - 6 millimetres and the expiration pressure as much as + 46 millimetres.

#### THE REACTION OF NORMAL SWEAT.

HEUSS (*Monatsschrift für Prakt. Dermatologie*, Band xiv., Nos. 9, 10, 12) first cleansed the skin thoroughly with neutral fluids and then collected the sweat in a watch-glass and carefully tested it. He found the sweat of healthy men during rest to be normally acid; but when profuse perspiration occurred, as after the administration of pilocarpin or of boracic baths, it became neutral or even alkaline. The reaction of the sweat is to be distinguished from the acidity that a section of the skin presents in all parts of the body, which extends as far as the prickle cell layer, for even when the sweat is alkaline the skin may be acid. The normal acidity of the sweat is the product of the less acid or possibly even alkaline secretion of the sweat glands and of the acid and cutaneous fluid; and its increase of alkalinity when the secretion is strongly excited by pilocarpin or heat depends essentially on the relative proportion of the sweat to the cutaneous fluid.

#### THE ACTION OF STRYCHNINE ON LEUCOCYTES.

IN this epoch of what may be called the apotheosis of the leucocyte we turn from phagocytosis to be met by researches on the action of certain drugs upon the leucocyte or to special histological appearances of the leucocyte under certain well-defined conditions. Ehrlich has provided us with much material for speculation as regards the latter, whilst in a series of *brochures* on experimental researches upon the leucocytes, Dr. E. Maurel<sup>1</sup> has contributed most remarkable observations in respect of the former. Those who have made themselves acquainted with the earlier fasciculi in which he dealt specially with the action of heat and cold upon leucocytes, and

have read the fasciculus in which he treats of the action of strychnine, curara, cyanide of potassium and hydrocyanic acid, will turn with interest to a similar series of researches on the action of strychnine, atropine, pilocarpine and cocaine. As regards strychnine, he maintains that the quantity of this drug required to kill an animal is equal to that required to kill the whole of the leucocytes in the body; and that the sensibility of an animal to strychnine corresponds exactly to the sensibility of its leucocyte to the same poison, and he holds therefore that in poison by strychnine the death of the leucocyte plays a most important part in the death of the animal. He finds that the same holds good in the case of atropine, and that in the case of the rabbit, which has such a well-known immunity from the action of belladonna, this immunity appears to be associated with the resistance of the leucocyte of the animal. This is a most important observation, and one that has a special bearing on questions that are being so vigorously discussed at the present day. As regards cocaine, he concludes that it brings about death either by saturation of the blood or by embolism; in the first case the cocaine apparently acts directly on the leucocytes, and the manner in which it poisons the animal corresponds very closely to that in which the other poisons act. In this book there is very much of interest from the purely biological point of view, whilst to the toxicologist and therapist it will probably prove exceedingly suggestive even when it is not more directly helpful.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Budapest.*—Dr. E. Jendrassik has been appointed Extraordinary Professor of Pathology, and Dr. Böke Extraordinary Professor of Aural Surgery.

*Erlangen.*—Professor Pechmann has been appointed Professor of Pharmacy and Director of the Pharmaceutical Institute.

*Giessen.*—Dr. Peter Poppert has been appointed Extraordinary Professor of Surgery.

DR. JOHN CHARLES STEELE, the Medical Superintendent of Guy's Hospital, died in that institution on Sunday, at the age of seventy-one. He was the author of "Vital Statistics of Guy's Hospital from 1854 to 1861," an "Analysis of Patients treated at Guy's Hospital from 1861 to 1868," "Hospital Diaries," &c., and was Howard Medallist of the Statistical Society for 1876 for his "Essay on the Mortality of Hospitals Past and Present."

AT the quarterly meeting of the Medico-Psychological Association, to be held at Bethlem Hospital on the 17th inst., Dr. Walmsley will advert to some observations made at the annual meeting at York; the discussion on Dr. Savage's paper on "Influenza and the Neuroses" will be continued; and Dr. Mercier will read a paper on "Payment of Patients for their Work."

A MEETING of the British Medical Temperance Association will be held in the rooms of the Royal Medical and Surgical Society on the 15th inst., when a paper will be read by Dr. Norman Kerr on Stimulants in Workhouses and a discussion on Children and Alcohol will be opened by Dr. Heywood Smith.

THEIR Royal Highnesses the Prince and Princess of Wales, who will be accompanied by the Duke of York, will on Dec. 14th open the new wing of St. Mary's Hospital, Paddington, which has been erected and named in memory of the Duke of Clarence and Avondale.

MR. WILLIAM ST. CLAIR SYMMERS, M.B., C.M., has been appointed Pathologist to the Aberdeen General Hospital.

<sup>1</sup> Recherches Expérimentales sur les Leucocytes. Octave Doin, Paris, 1892.

THE annual dinner of the Bristol Medical School will take place at the Royal Hotel, College Green, on Wednesday, the 16th inst. Sir Andrew Clark will occupy the chair on the occasion of the formal opening of the new medical wing at University College.

THE Grocers' Scholarship Lecture on "The Physiology and Pathology of Blood Destruction" will be delivered by Dr. William Hunter in the theatre of the Examination Hall, Victoria Embankment, at 4 P.M. on Tuesday, the 22nd inst.

THE next half-yearly dinner of the Aberdeen University Club, London, will be held at the Holborn Restaurant on Wednesday, Nov. 16th, at 7.30 P.M., Professor Ferrier, M.D., LL.D., F.R.S., in the chair.

THE trustees of the "George Henry Lewes Studentship" have elected Mr. J. Sydney Edkins, M.A., M.B., Senior Demonstrator of Physiology in the Owens College, to that foundation.

THE Royal Portsmouth Hospital has just received from the Mayoress of that town the sum of £132 10s. 11d., the proceeds of an entertainment given by her in aid of the hospital.

THE medical officers and instructors of the Volunteer Ambulance School of Instruction will hold their annual dinner at Cannon-street Hotel at 7 P.M. on Saturday, Dec. 10th.

SIR JAMES PAGET delivered a short inaugural address at the Oxford Medical Society, which held its first meeting in the University Museum on the 11th inst.

THE Westminster Hospital students' dinner will take place at the Criterion on Tuesday, Nov. 15th. Mr. James Black, F.R.C.S., will occupy the chair.

## INTERCOLONIAL MEDICAL CONGRESS OF AUSTRALASIA.

THE third session of the Congress was opened in Sydney on Monday, Sept. 26th, at 11 A.M., in the great hall of the University. The roll comprised 534 ordinary members, twenty-six honorary members and forty-three student members. The principal office-bearers were: Dr. P. Sydney Jones, President; Dr. T. Chambers, Treasurer; Dr. Anderson Stuart and Dr. S. T. Knaggs, Joint General Secretaries. The opening meeting was crowded, and was attended by the Governor, the Premier, the Primate and large numbers of the principal citizens, for the interest taken by the general public in the conference had been most keen. The Governor (the Earl of Jersey) welcomed to Sydney "men of that great science to which all men some time or other turn with many feelings of hope, at other times with fear, and always with gratitude," and said: "When they put their fingers on the pulse of Sydney, they would find it respond with an even and healthy beat to every sentiment of kindness and hospitality." Professor Anderson Stuart then read the report of the executive committee, which gave a brief *résumé* of the steps which had been taken since the second session at Melbourne in 1889. The report was adopted on the motion of Drs. Verco of Adelaide and Bright of Hobart. The Premier (Sir George R. Dibbs, K. C. M. G.) then followed up the kindly welcome which had been given by the Governor, and said that it struck him that it was "a most pleasing circumstance that amidst all the turmoil and storm—socially, commercially and politically—so large a number of medical men should have left their avocations in every colony to meet in Congress for the discussion of so many questions affecting the welfare of humanity as are embraced in the programme." The President then

delivered his inaugural address, in which he dwelt on the advances which had been made in medical science and art during the last forty years, the period during which he had been connected with the profession. At the conclusion of these proceedings the Governor announced that the Government would undertake the publication of the proceedings of the Congress, an announcement which was received with cheers. The meeting was then adjourned till the evening. In the afternoon the Mayor and Mayoress held a reception in the Town Hall, which was tastefully decorated with palms, ferns and flowers, and looked very fine. The great organ was played at intervals, refreshments were served, and the afternoon passed very pleasantly. The evening meeting was held in the Great Hall of the University and was entirely devoted to the discussion of the manner in which the executive had been appointed, and some very plain speaking was indulged in. In order to bring the matter up it had been arranged that Mr. Tarrant should move for a committee to consider and report on a matter of procedure to regulate the preliminary steps for future meetings. Mr. Tarrant, in moving for the committee, made upon this occasion an exceedingly even and temperate address; but, unfortunately, those who followed him gave free expression to their feelings. It was, however, quite apparent that the discontented party had no sympathy from the meeting, and the executive and that side of the house thought it best, in the interests of peace, to make no reply of any sort. The speaking was therefore all upon and for one side; but the voting was very different, for on division the discontented party was hopelessly out-voted. No regular counting was done, but it seemed to the writers that the minority was about 36, while the majority was considerably over 200. When once this matter had been got over nothing further occurred to mar the harmony of the session, which continued from day to day without a hitch. The weather on five out of the six days was simply perfect, so that the numerous outdoor festivities and excursions were not interfered with except in one unimportant case. The meetings of the Sections and Subsections were held in the various theatres of the medical school, which, being all in one corridor, were peculiarly suited to the purpose, for they followed in numerical order—(1) Medicine, in the Harveian Theatre; (2) Surgery &c., in the Hunterian Theatre; (3) Midwifery &c., in the Hallerian Theatre; (4) Public Health &c., in the Cullenian Theatre; and (5) Anatomy and Physiology &c., in the Vesalian Theatre; the subsections of diseases of the eye, and of the ear, nose and throat, in the smaller rooms. The papers were plentiful, over 160, and upon the whole of good quality. The impression is that they were decidedly better than at the last meeting. The Section sat usually from ten till one.

A *résumé* of the proceedings of the Sections will be given later on. On Tuesday afternoon the Governor and the Countess of Jersey gave a garden party at Government House. There were from 700 to 800 present, and the weather being delightfully fine the visitors greatly enjoyed themselves. On Wednesday afternoon, at the invitation of the Government, the members and their friends were conveyed in their steamer down the harbour to the quarantine station. Excellent refreshments were provided and again the weather was delightful, so that all returned well pleased with the outing. In the evening the President entertained about 400 at dinner in the Town Hall, and, in responding to the toast of his health, the Governor took occasion to say a few words on the necessity of upholding law and order. It is not often that governors in these colonies are called upon to speak on such topics, but the circumstances of the hour in Australia made his words most timely, and they were received by the lay assemblage with enthusiasm, testified by applause. On Thursday his Excellency was present to hear the presidential address in the Public Health Section, and afterwards visited the Section of Surgery; the question of hydatids was under discussion. In the afternoon a large party visited the Leper Hospital, where many of the visitors saw leprosy for the first time. The various forms of this disease were demonstrated by Dr. Ashburton Thompson. There are about twenty cases detained here, including two females and seven males, natives of Australia, of European descent, besides eleven Chinese, one Japanese, one Kanaka. The arrangements at the Leper Hospital are very complete; two wardsmen attend the males, two nurses the females, and in every way—by comfortable quarters, on a charming site overlooking the ocean, cheerful furniture, liberal dietary and allowances of "medical comforts"—the lot of the leper is tempered. In the evening the

orchestral concert to which the members were invited proved a most enjoyable treat. On Friday afternoon there was a harbour party to view the gardens and grounds of Gladesville Hospital for the Insane, probably the finest flower garden in Australia. Here also the park, with its herds of emus, kangaroos and wallabys, was most interesting. As good luck would have it, the final heat of a great sculling race was witnessed from the steamships, which then proceeded to the Thomas Walker Convalescent Hospital, which is approaching completion as a memorial to the late Thomas Walker. In the evening a *conversazione*, which was given by the members of the Congress, was held in the great hall of the University. Elaborate preparations had been made and the gathering proved a great success. The great hall was used as a museum, concert hall and refreshment room. The grounds were illuminated, and the chemical, physical, engineering, biological and geological laboratories, as well as the medical school, library, Nicholson museum, and, in fact, all the University buildings, were thrown open and lectures and demonstrations given and experiments conducted. About 1400 persons attended. On Saturday the final meetings of the Congress were held in the Harveian theatre, and a great deal of business was done, which we shall report hereafter. At noon a harbour excursion was given by the Congress to May Fern Bay, where luncheon was served; afterwards the visitors proceeded by steamers to some of the more beautiful reaches of the harbour. In the evening Drs. Chambers, Knaggs and McCormick entertained over 200 members at dinner at the Australia Hotel. Good music was provided instead of speeches till midnight, when the company separated after singing "God save the Queen." With that we conclude a general account of the proceedings. A *résumé* of the work of the various Sections as supplied by the sectional secretaries follows.

#### SECTION OF ANATOMY, PHYSIOLOGY, PHARMACOLOGY AND PATHOLOGY.

The presidential address was delivered by Professor H. B. Allen, University of Melbourne. The address was devoted to a comprehensive survey of recent progress in the subjects comprised in the Section. In special reference to the progress of pathology, the President reviewed at some length the modern doctrines relating to immunity, furnishing a critical exposition of various divergent views and indicating the lines of possible further advance, both in the investigation of the problems involved and in the therapeutical application of the principles elucidated. In connexion with the subject of anatomy the following were brought forward:—

Observations on the Normal Position of the Vermiform Appendix, by Drs. G. E. Rennie and Cecil Purser. In the paper Drs. Rennie and Purser communicated the results of their observations upon 100 subjects, partly confirmatory of and partly at variance with the results of other recent observers.

On Recent Progress in Microscopic Construction, with Demonstration of Modern Microscopic Apparatus, by Dr. Gustav Lennhoff. The speaker dealt fully with the principles of the improvements in microscopical objectives, oculars and illuminating apparatus, as illustrated in the apochromatic lenses and compensating oculars and substage optical systems of Zeiss, together with the other mechanical accessories of the modern microscope.

On Two Cases of Congenital Malformation of the Heart, by Dr. John Morton, Demonstrator of Anatomy, University of Sydney. The first case was one of entire absence both of pulmonary artery and ductus arteriosus; while the second case exhibited entire absence of left ventricle and of aortic orifice, the proximal part of the aortic arch being present as an attenuated but pervious cord, constituting a common trunk for the coronary arteries.

On the Closure of the Central Canal of the Spinal Cord in the Fœtal Lamb, by Professor J. T. Wilson, University of Sydney. In this paper the author adduced certain observations in support of the theory of the mode of production of the lumen of the central canal maintained by Balfour for chick embryos, and subsequently criticised adversely by other writers.

Exhibition of a Skeleton of a Dwarf; forwarded by Professor Watson, University of Adelaide, accompanied by notes on the life history and chief features of the case.

Dr. Lockhart Gibson (Brisbane) read a paper on the Functions of the Thyroid Gland with observation on a case of Thyroid Grafting, in which he insisted that the proof against

the alleged blood-forming function of the thyroid is sufficient. The history of the patient was adequately demonstrated by a series of photographs, showing the gradual advance of myxœdema for the first four years of life, and the very marked and steady improvement following the grafting of the thyroid of a lamb, which grafting took place in the fifth year—i.e., two years ago. Dr. Gibson also gave an account of the subsequent history of the lamb used, from which he imagined he had removed the whole gland. This animal showed no signs of cachexia eight months after the operation. It was then killed, and it was found that a small piece of the lower end of one lobe had been left. This had hypertrophied and carried on the essential function of the thyroid; sections made from this portion remaining showed a remarkable scarcity of lymph follicular tissue, but were otherwise of normal appearance.

Dr. C. J. Martin read a paper on the Effect of Food on the Secretion of Bile in Man, in which he showed that in the case observed there was a very marked increase in the rate of secretion, commencing about two hours after the ingestion of food, reaching a maximum four hours after and then rapidly declining. "Curves of flow" taken by allowing the bile to flow into a cylinder on the surface of the fluid in which was a specially devised form of float, the movements of the latter being registered on a revolving smoked cylinder, were shown. From a number of these curves Dr. Martin had differentiated a mean "curve of speed of flow" from which he derived his conclusions. The paper also contained an analysis of human bile from a fistula and remarks concerning the composition of fistula bile.

The President (Professor Allen) and Dr. T. Cheery contributed a short paper on the general plan of teaching practical pathology in the University of Melbourne, the notable feature being a course of practical bacteriology, "consisting of two hours' work twice a week for five weeks," that every medical student must attend.

Dr. J. Lockhart Gibson read a paper on a case of Pernicious Anæmia in a man aged fifty-six, in which he described red cells of various sizes, shapes and structures, resembling and—the speaker implied—even homologous with cells already described by him in his account of the development of the blood-cells in the bone marrow of the dog. He therefore concluded that pernicious anæmia had to do with defective or perverted production rather than excessive destruction of red cells. He also observed that, at least in old age, there is a rapid destruction—solution, as it were—of the red cells in the blood after it has left the vessels. This secondary destruction of cells may be a source of fallacy.

Dr. G. E. Rennie contributed a paper on Healed Pulmonary Tuberculosis.

Dr. W. Camac Wilkinson, Secretary to the Section, gave a demonstration of the bacteriological tests for the diagnosis of Asiatic cholera in suspicious cases, and exhibited pure cultures of pathogenic and other organisms, including those of the fowl as well as of human tubercle, tetanus, glanders and favus.

Through Dr. Wilkinson Mr. C. J. Pound showed beautiful growths upon agar and gelatine of the actinomyces fungus obtained directly from cases of actinomycosis, a disease very common in cattle in Australia; and Veterinary Surgeon Park (Tasmania) showed excellent microscopic specimens of the mycelium and clubs of the actinomyces, sometimes in combination, sometimes one or other alone. In one case of Mr. Park's a packing-needle, swallowed and transfixing the wall of the stomach, had become the starting-point of an extensive actinomycotic growth—a case of great etiological interest.

#### SURGERY.

The Section of Surgery sat four days, under the presidency of Dr. W. Gardner of Melbourne.

On the first day Dr. A. Shewen (Sydney) opened a discussion on Anæsthetics. He believed that the statistics possessed on such a subject were of little value and that for the future they should endeavour to follow the example which England had set them and establish their own clinical history. This he did not think should be compiled by the anæsthetist, but by a bystander, for fear that the unavoidable mental preoccupation might interfere with the safety of the patient. In the case of the medical school it should be done by students. In regard to the question of ether *versus* chloroform, he thought that each possessed advantages which are wanting in the others. A discussion followed in which eighteen speakers took part.

Dr. Springthorpe (Melbourne) thought that a large per-

centage of fatal cases was due to maladministration and advocated for the lighter forms of operation the use of what he termed *cortical* anaesthesia. This statement met with opposition from various speakers, who thought that the patient should be under the full influence of the anaesthetic, and that *cortical* anaesthesia should be confined to certain cases of midwifery.

The President, in closing this discussion, recognised the importance of the personal equation of the anaesthetist. As an operating surgeon he felt that with certain individual anaesthetists his mind was at ease, whilst with others he felt in constant anxiety.

Dr. MacCormack exhibited a case of Rhinoplasty operated on by the Indian method of the frontal flap, with this important modification: that before bringing the flap down he had prepared a cutaneous lining from the inside of the nose by raising two small flaps of skin on each side of it.

Mr. Cleghorn (New Zealand) read a paper on the Treatment of Acute Purulent Synovitis by washing out with Peroxide of Hydrogen; also on the Treatment of Chronic Abscess by Baker's Method.

Dr. Syme (Melbourne) followed next with a paper on Ganglion. As a result of numerous dissections and pathological observations he had come to the conclusion that in cases of simple ganglion rupture or incision might suffice, but that in cases of compound ganglion free removal of the diseased sheath was the only treatment advisable.

Mr. Poulton gave his experiences of Two Cases of Ankylosis of the Lower Jaw treated successfully by excision of the condyle.

On the second day the President delivered his address, an eloquent and exhaustive review of Modern Surgery. This was followed by a paper of Mr. G. E. Twynam (Sydney) on an Operation for Treatment of Dislocation of the Acromio-Clavicular Joint, and by one of Dr. F. Bird (Melbourne) on the Radical Cure of Hernia by a New Method.

The meeting was closed by the exhibition of a woman operated on two years ago by Dr. MacCormack (Sydney) for Scirrhus of the Pylorus. This extended for two inches within the first part of the duodenum, and was excised by Dr. MacCormack according to the Billroth method. The patient has enjoyed good health ever since, and does not present any sign of recurrence of the disease.

The third day was devoted exclusively to Hydatids—a subject of particular interest to Australian surgeons and physicians. After reading many papers an important discussion took place between the advocates of treatment by aspiration in the case of simple abdominal hydatids and those who in all cases prefer the radical cure by incision.

Dr. Verco read a suggestive paper on the Treatment of Hydatids of the Brain. He proved that one-third of all cases of hydatids of the brain communicate with the lateral ventricles, and as a result a large percentage of the fatal cases is due to draining the cerebro-spinal fluid and leaving the ventricles dry. To obviate this, he suggested that in future, after emptying the cyst through a trephine hole and washing out as usual, no drainage-tube should be left, and that the flap should be closely stitched and thus the cavity left hermetically sealed.

Mr. Spencer (Bathurst) made known the fact that he had treated two cases of abdominal tumours due to the *Bothrioccephalus liguloides*, of which one died and the other recovered. This is the first time that the presence of such a parasite has been recognised in Australia.

On the fourth day Colonel-Surgeon Williams (Sydney), in a paper on Military surgery, dealt with the characters of wounds caused by the new magazine rifle bullets. Two new methods of subcutaneous wiring for fractured patella were explained—one by Mr. Fitzgerald (Melbourne) and the other by Mr. Twynam (Sydney).

The treatment of Talipes also excited an interesting discussion between the tenotomists represented by Dr. Milford (Sydney) and those who believe that in certain severe and intractable cases bones should be altered in shape either by drilling according to Mr. Fitzgerald's method or by simple osteotomy. The question of tracheotomy in diphtheria was introduced by Mr. Clubbe (Sydney), who in 120 tracheotomies performed at the Sydney Hospital for Sick Children obtained 51 recoveries, and by Dr. Crago (Sydney), who out of 19 operations had 10 recoveries. Dr. A. Jefferis Turner (Brisbane) advocated intubation of the larynx and gave an account of 19 cases treated by such a method with 7 recoveries. Dr. F. Bird (Melbourne) ended the meeting by reading a case of injury to the median nerve due to a gunshot

wound, in which a portion of the sciatic nerve of a cat was grafted, with restoration of function.

The papers read were only one-half of those entered in the Section of Surgery, there being other twenty-eight papers that, through want of time, had to be taken as read.

#### SECTION OF OBSTETRICS AND GYNÆCOLOGY.

The President, Dr. Balls Headley (Melbourne), delivered a philosophic address on the Evolution of Disease in Woman and the Influence exerted by Civilisation, pointing out how the conditions of modern life evolve diseases in women which cause sterility, and thus limit the population as certainly, although to a less degree, as polyandry and other expedients of savage nations. Dr. Headley, as a sequel to his address, read a paper on the Treatment of the Inflammatory Affections of the Uterus and Appendages, laying special stress on the necessity for closing lacerations of the perineum or cervix, especially of the latter in view of the frequency with which cancer attacks cervixes which have been lacerated, also for establishing thorough drainage in endometritis and stenosis of the cervix by dilating with Hegar's dilators and curetting. Dr. Headley's views met with general acceptance from the members present.

Dr. Camac Wilkinson (Sydney) read a paper on Some Questions affecting Obstetrical Practice, in which he deprecated frequent vaginal examinations during labour and also the frequent use of the forceps, while he strongly advocated the immense advantages of external palpation.

On this latter subject Dr. Dick (Sydney) also read an able paper.

Dr. Pinnock (Ballarat, Victoria) brought forward a New Method of Operating for Large Ventral Hernia, which consisted of splitting the sheaths of the recti muscles and bringing the muscular fibres together instead of the tendinous structures. In this operation the peritoneum is not opened. The results had been very good.

Mr. Cleghorn (New Zealand) read notes on a case of Ovarian Abscess producing symptoms simulating those of ectopic gestation.

Dr. Worrall (Sydney) showed Ectopic Fœtuses, successfully removed by abdominal section; one was removed during a superadded normal pregnancy. Three of the patients had since gone through subsequent pregnancies normally. He also read a note on Trendelenburg's position.

Dr. MacSwiney (Sydney) read notes on two instances of Protracted Gestation in the same patient. Her second pregnancy lasted 330 days from last menstruation, and in her third pregnancy labour was induced 298 days after. He considered inertia of the uterus to be the chief cause.

Dr. Thring (Sydney) brought forward four cases of Vaginal Hysterectomy for Cancer. All had recovered from the operation, but return had taken place within two years in two cases. He urged early removal.

Mr. Foreman (Sydney) showed a remarkable specimen of Fibro-cystic Disease of the Uterus involving the whole organ and having its lower portion extruded through the crevice. He had performed total extirpation of the whole uterus by abdominal section.

There were other valuable papers on Vesico-vaginal Fistula, by Dr. Fitzgerald (Melbourne); Dilatation and Curetting of the Uterus, by Dr. J. A. G. Hamilton (Adelaide); Pessaries, by Mr. Edgelow (Sydney); Surgical Treatment of Uterine Tumours, by Dr. Leichelmann.

#### PUBLIC HEALTH.

An introductory address was delivered by the President, Dr. Whittell (Adelaide), in the presence of his Excellency the Governor (the Earl of Jersey). Dr. Whittell's subject was a comparison of the health codes of various colonies with the practical results attained under them. In the course of a very interesting paper he showed that the means and results were incommensurate, and traced the defect to general apathy and pressure of local interests as regards the local authorities charged to execute the laws on the one hand, and, on the other, to lack of power vested in a central authority to step in and compel the local bodies to do their duties. The most important of the thirteen papers read in this Section was that by T. A. Coghlan, Esq., Government statistician, on a Life Table for New South Wales, which he has just deduced from the results of the census of 1891, and the mortality of the two years ending March 31st, 1892, the results being adjusted according to the system devised by Mr. W. S. B. Woolhouse. Mr. Coghlan showed that the expectation at birth was: males 49.6 years and females 52.9 years, and that it was highest at two years

of age, when the expectations were respectively 56.37 and 58.74 years. These figures are much higher than those given in Dr. Ogle's table for England—a result which, as Mr. Coghlan properly pointed out, is probably due to the more favourable conditions under which the inhabitants of a new and not yet overcrowded country are brought up.

Dr. David Hardie (Brisbane) contributed a remarkable paper, in which he compared the varying number of deaths from several diseases at different seasons of the year with the meteorological conditions observed at those seasons in each of eight districts into which he divided the whole colony for this purpose. A chart which must have taken many weeks to prepare showed in graphic form the remarkable coincidences which he desired to point out.

Dr. Bancroft (Brisbane) contributed a paper on the History of Leprosy in Queensland, from which it appeared that the earliest recorded and known case occurred in 1866 in a German who had long lived in Hawaii; and Dr. Bancroft, after searching hospital records, is convinced that several undiagnosed cases in Europeans occurred later than the year named.

Other papers of importance were a Note on Worm-nests occurring in the Cellular Tissue of the Brisket of Cattle, by Dr. Gibson (Windsor, N.S.W.); Registration of Stillbirths and Protection of Infant Life, by Dr. G. L. Mullins (Sydney); the Diseases of Samoa (among which leprosy does not appear, only one visitor, a Hawaiian, having ever suffered), by the Rev. Dr. S. H. Davies (Tutula), medical missionary; the Course and Cause of Influenza, by Dr. Carstairs (Geelong, Victoria); and remarks on Tubercular Phthisis, by Mr. G. L. Lawson (Gosford, N.S.W.). Other papers were contributed from New Zealand and Thursday Island; and all but one or two were of important practical interest. Lunacy was taken in this Section, one day being devoted to the subject.

Dr. Chisholm Ross, of the Asylum for Imbeciles at Newcastle, N.S.W., spoke of the statistics of insanity in relation to the census of 1891, and concluded that the proportion of cases to population was diminishing, and was specially small amongst the native born.

Drs. McCreery and Stele (Kew) and Dr. Rosenblum (Yarra Bend, Victoria) read papers on Juvenile Insanity, Hydrocephalic Idiocy and General Paralysis, in which latter Dr. Macandrew of Hokitika, N.Z., also joined.

The most interesting transaction in this department was a discussion on Criminal Responsibility of the Insane, which was introduced by Drs. Springthorpe and Mullens (Victoria).

Dr. F. Norton Manning, Inspector-General of the Insane, N.S.W., made an important contribution; and a committee was appointed to consider the form which a resolution on the subject, to be presented to the general Congress, should take.

The following resolution from Section 4 to the Congress was adopted at the general meeting: "That in view of the fact that the present recognised legal test for insanity is false in theory and unsatisfactory in practice, and that the legal authorities have expressed a desire to obtain an expression of medical opinion upon the subject, this Section submits for ratification by the General Congress the following resolutions:—1. That it is impossible to frame any one test for insanity in criminal cases which is capable of general application. 2. That for criminal cases it would be in accord with present medical opinion to define insanity as a disease of the brain affecting the intellect and also the emotions and the will, not immediately induced by the default of the individual, leaving the following questions for the jury:—(a) Had the accused at the time of committing the act such disease of the brain? (b) If so, did such disease prevent in relation to the alleged crime—(1) a knowledge of the nature and quality of the act he was doing—(2) a knowledge that the act he was doing was wrong (illegal)—(3) a free determination of his will?"

#### MEDICINE.

The work of this Section began on Tuesday, Sept. 27th. Dr. James Robertson, consulting physician to the Melbourne Hospital and formerly lecturer in medicine in the Melbourne University, took the chair as president of the Section, and delivered an interesting address dealing mainly with the administration of chloroform as an anæsthetic. He took occasion to criticise the result of the Hyderabad Chloroform Commission. He gave a summary of his own experience, extending over forty-five years, and pointed out the practical importance of observing the pulse as well as the respiration.

Dr. John Gibson (Windsor, N.S.W.) read a paper on a case of Progressive Muscular Atrophy with unusual Cord Lesions,

illustrated by sections of the cord shown by Dr. Quaife by means of a projecting microscope and electric light.

On the 28th Mr. James Ryan (Melbourne) contributed a paper on the Etiology, Prevention and Treatment of Phthisis, which evoked a lively discussion.

Dr. Jeffries Turner read a paper on Chronic Lead Poisoning among Children in Brisbane, contributed by the Hon. Staff and Resident Surgeon to the Hospital for Sick Children in that city. He dealt with numerous cases attributed largely to the "tin-foil wrapping of sweetmeats." A discussion ensued.

On Thursday, the 29th, the first business was a paper by Dr. Fleming (St. Arnaud, Victoria) on Two Cases of Emphysema in Children mistaken at their onset for cases of peritonitis. The cases were marked examples of absence of pleural symptoms during the early stages of the disease, and presence of violent abdominal symptoms, marked tympanites and extreme pain. A discussion followed.

Mr. Bickle (South Australia) read a paper on Diabetes, with a case of recovery from diabetic coma by the use of oxygen.

Dr. Molloy, medical superintendent of the Melbourne Hospital, contributed a paper entitled, "Is Beri-Beri endemic in Melbourne?" The cases were those of a number of Chinamen simultaneously attacked by the disease while working in the same workshop. The symptoms were those of peripheral neuritis plus œdema, beginning in the lower limbs and becoming more or less general. An interesting discussion took place, from which it appeared that somewhat similar cases were found among the Chinese in Sydney.

On Friday, the 30th, a discussion took place on the subject of the Treatment of Snake-poisoning by Strychnine. In the absence of Dr. Mueller, the author of this method in Australia, a paper by him on the subject was printed and circulated among members. Dr. Huxtable read a paper dealing statistically with the result obtained among cases so treated. An interesting discussion on the whole subject was interrupted on account of stress of other business.

Dr. Struthers contributed a paper on Some Points in Connection with Small-pox. The paper contained many original observations, especially on the characteristics of the various initial rashes. Owing to lack of time this paper did not receive the discussion which its merits deserved.

Dr. Fleetwood (Warmambool) read a paper on Chlorosis, of value as a record of personal experience in treatment.

Mr. Springthorpe (Melbourne) read a paper on Eighteen Months' Experience with Tuberculin, in which he recorded his extensive experience of this method of treatment in phthisis with considerable success. Owing to lack of time the following papers which had been contributed to this Section were taken as read:—

1. Spinal Irritation, by Dr. Jarvie Hood (Sydney).
2. A Form of Cerebral Disease characterised by Definite Symptoms, probably a Localised Basic Meningitis, by Dr. Jeffries Turner (Brisbane).
3. Hypnotic Suggestions and their Therapeutic Value, by Dr. Arthur (Sydney).
4. Treatment of Asthma, by Mr. Turner (Melbourne).
5. Rôtheln, by Dr. Patrick Blackall (Queanbeyan).
6. Notes on the Occurrence of *Ancylostomum Duodenale* in Queensland, by Drs. Lockhart Gibson and Jeffries Turner (Brisbane).
7. Pearl Diving from a Physician's Point of View, by Dr. Salter (Thursday Island).
8. Notes on a case of Syphilis of the Heart, by Dr. Finschi (Sydney).
9. The Treatment of Hepatic Colic by large Doses of Olive Oil, by Dr. Sydney Jones (Sydney).
10. A case of Chylous Ascites, by Dr. Lendon (Adelaide).
11. On the supposed relation between Human Diphtheria and an Outbreak of Disease which was very fatal among swine in Geelong last year, by Dr. Paynter-Sloggett (Melbourne).
12. Remarks on 750 cases of Skin Disease, by Dr. A. W. Finch Noyes (Melbourne).
13. Reclamation of Nailbed and Treatment of Hirsutes by Electrolysis, by Dr. Herman Laurence (Melbourne).
14. Movable Kidney, by Dr. Dunbar Hooper (Melbourne).
15. Sequel to a case of Cerebellar Tumour, with exhibition of specimen, by Dr. Maudsley (Melbourne).
16. The Electro-neurotome, a new method of applying electricity, by Dr. O'Neill (Sydney).
17. Disinfection of the Alimentary Canal, by Dr. Creed (Sydney).

MEDICAL MAGISTRATES.—Mr. Thomas Walker, M.R.C.S., Wakefield, Dr. John Roberts, Chester, and Mr. James Taylor, F.R.C.S., L.R.C.P. Lond., L.F.P.S. Glasg., also of Chester, have been placed on the Commission of the Peace for the West Riding of the County of York and the City of Chester respectively.

## CHOLERA.

## CURRENT NOTES, COMMENTS AND CRITICISM.

THE reports this week as regards cholera are satisfactory. The warm weather which prevailed a few days ago seems to have given rise to a slight recrudescence of the epidemic generally, but it was of a very temporary character. At Hamburg the disease has ceased, and we learn from Berlin that the Ministry of the Interior has issued a circular cancelling all the special regulations enacted with reference to passenger and goods traffic with Hamburg, as the gradual and almost complete disappearance of cholera in that city justifies the abandonment of restrictive measures. From the Hague we learn from the official cholera bulletin that there have been only 27 deaths from the disease throughout the country during the week ending the 7th inst. Of these, 5 occurred at Ysselsteyn, in the province of Utrecht, 3 in the town of Utrecht, 5 at Breda and 3 at Huissen, in Gelderland. Four cases of cholera are reported from Rotterdam as having occurred among the crew of a fishing boat that arrived at Maassluis on the 4th inst. The outbreak at Breda was attributed to the infection of the water-supply, but the evidence on which this conclusion was arrived at is not stated, and there is always a disposition to assign any cause that may for the moment be plausible or popular without any due investigation. There is no doubt as to the important part played by a foul and contaminated water-supply in cholera, but the facile process of labelling an outbreak with this as the cause is too tempting to be resisted. It saves time and trouble, and is often promptly done without any pretence to exact inquiry. The Sanitary Board of the river Scheldt have decided that arrivals at Antwerp from Dutch ports, including Amsterdam and Rotterdam, shall only undergo a medical inspection and twenty-four hours' observation. In the case of French vessels, however, the existing regulations remain in force. At Budapest the disease has decidedly diminished; for whereas the seizures were, at the time of our last week's report, from 20 to 30 daily, they have now decreased to 8 and 10 in the twenty-four hours; 9 cases of cholera and 3 deaths occurred on the 6th inst., on a farm in the village of Lizesany in Hungary. It is as to the origin and causes of a limited outbreak of this kind in a village that we require precise information, for the exact circumstances and conditions should be capable of being unravelled by investigation. At Monville, near Rouen, there were 4 cases of cholera on the 6th inst., of which 3 terminated fatally; at Liege 5 deaths from cholera have occurred up to the present, and 7 cases are still under treatment. Five fresh cases of cholera and three deaths were reported at Brussels on the 5th inst. from the suburb of Molenbeck. At St. Petersburg sporadic cases of cholera continue to appear; on the 5th there were 4 fresh cases, and on the following day (6th) 7 cases and 1 death occurred. The disease has not only greatly declined, but its severity is less; there are fewer fatal cases. Cholera is still prevailing in Persia, at Ispahan, and in the villages round Shiraz.

A brief but interesting account of the cholera epidemic in St. Petersburg is published in the *Medical Magazine* for the present month, from which we glean the following information. The disease was first officially notified as present in Astrakhan on June 18th and at Nijni Novgorod on July 11th. Moscow first appeared in the official list on July 24th and St. Petersburg on Aug. 1st. St. Petersburg is built partly on the banks of the river Neva and partly on a series of islands at its mouth. No part of the Russian capital lies more than a few feet above the sea level, and the level of the ground water in St. Petersburg varies greatly. The water-supply is derived from the Neva at a point within city limits, and is consequently liable to pollution. The sewage is distributed over the fields in the neighbourhood and is not openly discharged into the river. It appears that, as early as July 20th, a number of patients suffering from diarrhoea and vomiting, attended in some cases with cramps were admitted into hospital. Up to July 29th, however, no comma bacilli had been found in any of the cases examined. These were discovered in the dejecta of a patient who was attacked on the 24th and died on the 25th of July. On Aug. 1st there

were 21 cases and 13 deaths recorded in the official list; and from this date the number slowly increased, the highest number of new cases being 156 in the twenty-four hours ending at noon of August 17th.

Many objections have been urged from time to time against the acceptance of the comma bacillus as *the* cause of cholera, and it must be confessed that some of them have much force. It must be remembered that the medical profession and sanitarians, both here and on the Continent, have had experience of previous epidemics. As John Stuart Mill remarked, it often happens that as one portion of the truth rises another and older portion sets, and previously recorded observations and deductions are apt to be entirely lost sight of later on. We sincerely trust that efforts will be made at the present time, not only to reach the substratum of facts, but to bring them into harmony with the latest views by bacteriological and other investigations. *En passant* we may here refer to the proposal of the Government of the Hague to provide a special grant for the purpose of instituting scientific inquiries in this respect. Cholera exhibits many different manifestations: it is endemic, epidemic and sporadic. It is not at all an uncommon occurrence at certain seasons, in India, for example, for one case of cholera, and one only, to appear and prove fatal in a small community of persons living with all things in common; and there are numerous instances of isolated limited outbreaks of the disease which have arisen and terminated in a few days. If the comma bacillus be a specialised object and only to be differentiated from other bacilli of similar appearance by cultivation tests, it is confessedly difficult to understand how its presence originated these occurrences, and how it had such a limited range of action. The relation of cholera to season, place and soil also requires further elucidation. That there are several places which have hitherto escaped cholera, notwithstanding the extent and frequency of their communications, indicates that the spread of the disease is subordinated to some complex agencies which have not yet been demonstrated or thoroughly explained. Cholera spreads along rivers, and low-lying districts and neighbourhoods are its favourite habitats. While it has some etiological affinities with typhoid fever it has also others with malaria as regards its connexion with porous soils, heat and moisture, and the want of proper subsoil drainage with super-added soil contamination. The broad facts have a certain bearing on Pettenkofer's well-known ground water theory. We would here call attention to the instructive cholera and typhoid fever maps of Havre illustrating the text of our special correspondent's communication regarding cholera in France. The prejudicial effect of recent constructions which served as dams to check the natural flow of the subsoil water, where the subsoil was constantly contaminated by the *bétoires*, on districts of the town which were previously healthy, is strikingly set forth, and might be easily paralleled by similar examples in other countries. In tropical and semi-tropical countries, where similar constructions, or the erection of railway embankments, have checked the natural flow of the subsoil water and given rise to a waterlogged condition, the liability to malarious disease has vastly increased; and where animal and sewage filth has been superadded to the moisture, other diseases, such as typhoid fever and diphtheria, have manifested themselves. It may be regarded as a sanitary axiom that there is a close connexion between the prevalence of cholera in a population and the unwholesome and contaminated water-supply with which that population is provided; but because this is established it will not cover the whole ground, for cholera indubitably may and does attack persons whose drinking water is good. It is apparently the case that the use of impure water of any kind in times of cholera prevalence may excite and precipitate an attack of that disease. In some of these cases it is a matter of extreme difficulty, if not of impossibility, to explain how the water obtained its specific infection. Bacteriologists do not seem to have yet determined the exact stage of the disease at which comma bacilli can be discovered in the dejecta. All seem agreed that these cannot be found in the blood or organs and tissues of the body generally; and the statements of Dr. Koch and Dr. Klein are at variance as to the number of comma bacilli being in proportion to the virulence and rapidly fatal issue of the cholera attack, for the latter says that in these speedily fatal cases they are found in small quantities only if the post mortem examination be made very soon after death. Many of these points should be capable of being cleared up by researches at the present time.

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

## A VISIT TO HAVRE.—PART III.

THE CHOLERA CENTRES OF HAVRE.—TYPHOID FEVER AND SUBSOIL DRAINAGE.—SEWERS AS A CAUSE OF DISEASE.—CHOLERA AND TYPHOID MAPS.

AT the foot of the hills and cliffs, which are about 300 feet high and face the sea to the west and then run inland in an easterly direction, a low-lying stretch of flat ground has been formed, and here is built the town of Havre, on soil redeemed from the mouth of the Seine. The town stands at the point of the angle formed by the sea to the west and the Seine to the south. The upper crust of the elevated ground is composed of a thin stratum of yellow clay resting on red clays mixed with silicious pebbles. This disposition of the soil varies in depth from thirty to eighty feet, and below there is a calcareous and clayey mixture. There are no impediments to the natural drainage of the soil, which is easily effected. The lower levels are more mixed in character, in consequence of landslips, and here there are springs of water. The plain on which the town of Havre is built consists of banks of pebbles brought by the northerly currents of the Channel and deposited under the shelter of the cliff of St. Adresse. Here the pebbles were mixed with clay and earth brought down by the river Seine. Vegetation soon appeared, being watered by the springs that descended from the higher levels. This ground is therefore of very recent formation, is almost on the same level as the sea, and it is only necessary to dig for some four to six feet to find water. Indeed, when the sea walls were built the most important portion of the town developed itself on ground that is below the level of the high spring tides. Roughly speaking, if a straight line were drawn from the railway station, passing behind the Hôtel de Ville on to the sea beach, the whole of the crowded district to the south will be found to be below the level of the spring tides.

North of the harbour—the Avant Port, or Tidal Port—there are three districts, all three triangular in form, to which I would draw special attention (1, 2, 3 in Map II.). The first, to the east, is called the Quartier St. François. It is a sort of island, surrounded on its three sides by the docks, or "Bassins de la Barre, du Commerce et du Roi." About a third of the length of the streets in this district have sewers which fall into the port. The second and middle triangular district is named after the church of Notre Dame. It forms an acute triangle, with the port for its narrow base; the Rue de Paris and the Bassin du Roi constitute the other two sides. For the third district the point of the triangle commences at the entrance of the harbour; there is the Rue de Paris on one side, the new and handsome Boulevard François Premier on the other side, and we may take the Rue de la Maillerie as the base of the triangle. This is the Quartier St. Joseph. There are but few sewers in these quarters, the streets are very narrow, the houses high, the population dense and poor, and it was in these three districts that the cholera found the greatest number of victims. The other cholera centres were to the north-east of the town, where is situated the suburb of Granyville, and the south-east of the town in the Eure district (4 and 5 in Map II.). These are the five centres of the cholera epidemic.

Bearing these facts in mind, let us now examine the drainage of Havre. About this a great deal has been said, but little or nothing has been done. It was in 1884-85, during the last cholera epidemic, that the matter was most seriously discussed, and no fewer than five schemes, fully elaborated, were submitted to the municipality. It was then ascertained that the streets measured ninety-eight kilometres and the sewers only twenty-six kilometres in length. Thus, the streets of Havre for more than two-thirds of their extent were without sewers. The town engineer assures me that this condition of affairs has not been altered. There may be one or two kilometres more of sewers than there were eight years ago, but there is also an increase in the number and length of the streets. Nothing whatsoever has been done. Worse than this, the most expensive and the largest of the sewers that had been built did more harm than good. A large main sewer, which has a fall of only 0.001 per metre, was constructed along the Boulevard de

Strasbourg: a splendid thoroughfare running along the town from the sea inland—that is to say, running parallel with the hills, not with, but across, the incline. This sewer, placed athwart the natural drainage of the subsoil, checked the flow of the underground water currents. The result was marked and almost instantaneous. The district north of the Boulevard de Strasbourg consists for the most part of villas and houses inhabited by persons in easy circumstances, and was a remarkably healthy quarter. Typhoid fever especially, though widely prevalent in the lower parts of the town, was unknown in this most favoured neighbourhood. After the building of the sewer, to the consternation of the inhabitants, a number of cases of typhoid fever occurred north of the Boulevard de Strasbourg. No one, however, suspected the sewer; on the contrary, the cry arose for more sewers. Then a second main sewer was built further north, along the Rue Frédéric Bellanger, the Rue d'Étretat, Rue Fouache and the Rue St. Thiébault. This sewer, again, cut right across the line of natural drainage. The fall is from north to south; both these main drains run from east to west. Once more the same phenomenon produced itself; the district on the higher levels beyond this second main sewer in its turn became infected with typhoid fever—a disease which previously had been unknown to the inhabitants. Cases occurred in the mansions of the wealthiest inhabitants of Havre, built on the beautiful slope that rises up towards St. Adresse. M. Siegfried, the representative of Havre in the French Parliament, and for some time Mayor of Havre, was one of the victims. When at the last extremity his life was, however, saved by the transfusion of blood, an operation performed by Dr. Gibert. These sewers are shown in Maps II. and III., and it will be seen how numerous are the cesspits and the cases of typhoid fever north of these sewers, in districts where the fever was formerly unknown.

To fully understand the mischief that was done by building large sewers which in practice became walls serving as a dam to check the natural flow of the underground water-courses it must be explained that there are at Havre some 600 *bétoires*. The word *bétoire* is a provincial corruption of the French words *boit tout*. A *bétoire* is a sort of well or pit which "drinks all" that is thrown in. It is a cesspit with walls made as porous as possible, so that all the liquids thrown in immediately percolate the subsoil. In these leaking pits are drained all the slop and kitchen water. In the central and southern parts of the town the slop water drains into the gutters and the sewers; but in the higher and northern sections of the town—the very districts situated beyond the main sewers described—most of the houses have *bétoires*. Formerly the water that leaked out of these pits drained away into the lower town, and thence into the port and the sea. Now, this natural flow was stopped by the walls of the main sewers, and the quarters affected were soon invaded by typhoid fever.

Thus, districts which were exceptionally healthy have become less healthy, and districts formerly totally exempt from typhoid fever became susceptible to this disease when the walls of the new sewers checked the natural flow of the subsoil water. Though in these districts the subsoil was constantly contaminated by the *bétoires*, the fact that the ground was elevated and that there was a good fall ensured the prompt removal of this nuisance. On the other hand, south of the Boulevard de Strasbourg the ground is flat, there is no natural drainage for the subsoil, and there typhoid is endemic, diphtheria has prevailed extensively and the cholera has wrought havoc. Yet there are no *bétoires* south of the Boulevard de Strasbourg, except at Le Perroy, a particularly healthy district west of the Boulevard François Premier. *Bétoires*, however, are not necessary to the contamination of the subsoil. We have seen that but few streets have sewers. The slop water of the houses does not even drain into the gutters, but goes first into the back yards; and thence flows to the street gutter, but before reaching the street gutter a good deal of the water has sunk into the soil of the yards, and more sinks into the soil of the street, for the gutter may travel a long distance before it reaches the gutter of some other street where there may be a sewer. It is only necessary to visit these quarters to see the enormous quantity of liquid filth which form stagnant puddles and pools in the yards, passages, courts, alleys, and streets. In the poorer and dirtier quarters this slop water often contains fecal matter. The inhabitants employ vases instead of frequenting the closets, and empty these vases where only slop water should be thrown. The closets are generally so extremely filthy that it is not surprising if many persons seek to avoid them. In

MAP II. — TYPHOID FEVER.

Topographical Map, showing the position of the houses inhabited by persons who died from Typhoid Fever from the 1st of January, 1887, to the 31st of December, 1888. There were 499 deaths in 1887 and 283 in 1888, and also 24 deaths at the hospital of persons who gave no address

1. The Quartier St. François  
5. The Granville District

2. The Quartier Nôtre Dame.  
6. The Railway Station.

3. The Quartier St. Joseph.  
7. The Hôtel de Ville

4. The Eure District.  
8. The Perrey District.

MAP III. -- CESSPITS.

MAP OF THE BÉTOIRES, OR LEAKING CESSPITS OF HAVRE,

Showing that these leaking cesspits are situated for the most part on the higher ground to the north of the two main sewers. The cesspits will also be noted in the Eure District to the South-East and in the narrow Parrey District to the West, with its long sea front and tidal flushing of the subsoil.

all the poorer houses I have visited there were pail closets, with no ashes; nothing whatsoever to mitigate the nuisance. In other houses there are cesspools as in Paris and many large French towns, but some of the houses drain direct into the sewers.

At the Bureau d'Hygiène every case of cholera was marked on a large ordnance map by a pin. At my request and for the special benefit of the readers of THE LANCET a black spot was painted on the places inhabited by each person who had died from cholera. The map thus marked was photographed, and is now reproduced on p. 1125. In looking at this map no notice need be taken of the rows of spots to the north where the hospital stands. The deaths that took place at the hospital are recorded at the houses whence the patients were removed. The cholera map shows at a glance that the three triangular districts I have described have suffered the most. It also shows that the district to the east of the Hôtel de Ville, a central district, has been almost entirely exempt from cholera. (The Hôtel de Ville is marked 7 in Map II.) Here the streets are wide, they are better drained, and the Boulevard de Strasbourg slants in a somewhat more southerly direction, so that the main sewer built under this boulevard is not quite at right angles with the line of flow of the natural subsoil drainage. What is also very remarkable is the comparative immunity from cholera in the narrow and long Perrey district west of the Boulevard François Premier (marked 8 in Map II.). Nothing can be more wretched than this neighbourhood. The people who live here are just as poor as those who live in the poorest streets of the St. François or Notre Dame districts. Their houses are as badly built and have the extra defect of possessing numerous *bétoires*. All that can be said is that the houses are not so high or so crowded together. The death-rate here is nevertheless much below the average of the town. Few cases of diphtheria and of typhoid fever have occurred, and the cases of cholera are scarce when compared with what has happened in other places peopled by the same class of persons. Dr. Gibert has prepared a map on which he has marked the deaths during the great typhoid fever epidemic of 1887 and 1888 (see Map II.). There were then 697 deaths from typhoid fever. It will be seen that during the typhoid fever epidemic, as also during the cholera epidemic, this district of the Perrey was equally exempt. Dr. Gibert conjectures that such immunity is due to the fact that the subsoil at Perrey is flushed out twice a day by the tide. This narrow strip of ground protrudes into the sea, receiving the full force of the currents. On the other hand, if we take the three triangular districts to the north of the port, it is easy to see that they are not washed by any subterranean current. There is a tide in the port, but this is carefully walled round by quays.

If we compare the map of the typhoid fever epidemic with that of the cholera epidemic, we shall be at once struck with the similitude of both maps. They are so much alike that it is very difficult to distinguish the one from the other. Dr. Gibert has drawn other maps for other diseases, notably for diphtheria and for phthisis, and he finds that they also bear a startling likeness to the typhoid fever and cholera maps. It is the same streets and the same districts that suffer most from these very different diseases. What is the cause of this remarkable phenomena? In the poor, dirty, badly built district of Perrey the St. Laurent water is drunk, and there is little or no cholera or typhoid fever. In the St. Joseph, the St. François and the Notre Dame districts, where very poor people dwell, the St. Laurent water is used, and there is an appalling prevalence of typhoid fever and of cholera. At the barracks, where 1200 soldiers are garrisoned, and at the prison, with a population of 550 persons, the St. Laurent water is consumed and there is not a single case of cholera. At the huge block of buildings where 600 custom house officers live, and with their families constitute a population of about 3000 persons, the St. Laurent water is taken, and there have been but two doubtful cases of cholera. These buildings are near the better drained central district to the east of the Hôtel de Ville, where the St. Laurent water is drunk, and where the cholera and typhoid fever have done little or no harm. In almost all parts of the town the same water is consumed, yet the prevalence of cholera is very unevenly distributed. Nor does the cholera always spread in very poor, wretched old houses, otherwise the Perrey district would not have escaped. Two causes seem to exist which apply to the districts especially affected and not to the other parts of the town. The first is the want of proper subsoil drainage—in other words, a long-standing contamination of the subsoil unrelieved by natural

drainage. This cause may be taken to apply to the five chief cholera districts, the three triangular districts, the Granville district, to the north-east, where the cholera began, and to the Eure district in the south, where there are a great many *bétoires*. The second possible cause applies more particularly to the first three districts than to those of the Granville and Eure—it is the want of air in the streets; in other words, the height of the houses and the narrowness of the courts and streets. In this respect, if we look at the houses on the Grand Quai facing the harbour and the Boulevard de Strasbourg we find no deaths from cholera, or at least only one death on the Boulevard de Strasbourg. The death marked on the Grand Quai occurred in a back yard. In the broad Rue de Paris, the busiest street of the town, there was but one death. Where the streets are broad and well swept by the sea air there are few or no deaths from cholera. This is especially remarkable with regard to the Grand Quai and the Rue de Paris, the worst streets being behind the Grand Quai and by the side of the Rue de Paris. It would seem from this that there is relatively little danger in living in close proximity to cholera districts if the house inhabited has a plentiful supply of air and an open space in front. Even without these essentials to health the better drainage of the subsoil might produce the most beneficent results. Dr. Gibert especially insists on the fact that when a pure water-supply was brought to Frankfort typhoid fever still continued. It was only much later and after the town had been thoroughly drained that typhoid fever ceased. Perhaps, if Havre were properly drained and the contamination of the subsoil prevented, typhoid fever would disappear and cholera would not again be able to break out in an epidemic form.

Undoubtedly a complete system of drainage is an imperative necessity. The death-rate of Havre is the sure evidence of the bad sanitation of the town. The death-rate for the ten years 1880-89 was 30.9 per 1000 of the population; the birth-rate during the same period was 32.8 per 1000 of the population. In the northern (Canton Nord in maps), or wealthiest division of Havre, the birth-rate was 27.6 and the death-rate 27.9 per 1000. In the southern (Canton Sud in maps) district the birth-rate was 31.6 and the death-rate 32.1. In the eastern (Canton Est in maps) district the birth-rate was 39.8 and the death-rate 33.2. Thus, where there was the greatest poverty and the highest death-rate, the population increased the most, while in the healthiest and most wealthy division of the town the birth-rate was a little below the death-rate. In the northern division live the merchant princes; in the southern division labourers and sailors; in the eastern division artisans, workmen and Brittany navvies. But the most striking contrast will be found if death-rates of various streets are compared. For instance, the death-rate in the Rue François Premier is only 12.03 per 1000, whereas, not far off, in the Rue Marbonne, the death-rate reaches the alarming proportion of 57.2 per 1000. When such variation occurs, we may be sure that proper sanitary measures would, in a great measure, remedy the evil. In any case, it is now clear that the interference with the subsoil drainage has done great harm, and that where the underground waters stagnate there disease is most prevalent and there the cholera found its home and its readiest victims.

## THE ETHICS OF OPIUM.

*Deputation to Lord Kimberley.*

ON Thursday afternoon, at the India Office, a large deputation, representing the Society for the Suppression of the Opium Trade, the Women's Anti-Opium League, the Baptist Missionary Society and a number of other organisations, waited upon Lord Kimberley, the new Secretary of State for India.

Sir JOSEPH PEASE, M.P., introduced the deputation and in the course of his remarks spoke of the Indian Government being engaged in an immoral trade which ought to be put down speedily and with vigour.

Mr. J. G. ALEXANDER, Secretary of the Society for the Suppression of the Opium Trade, presented a memorial to his lordship which had been prepared on behalf of the Society. This memorial asserted that the emphatic condemnation of the opium trade pronounced by the Members of the late House of Commons was the result of a widespread feeling amongst the most thoughtful people of this country, and especially

amongst the Christian churches hostile to the continuance of the opium trade at present carried on by the Indian Government. The public conscience was shocked, not merely by the sad and shameful record of the wars by which the legalisation of this traffic was wrung from China, but by the continuing fact that the British nation raised revenue wherewith to provide for the cost of governing India by trading in an article which was prepared for vicious use, which brought misery to countless myriads in China and other Eastern lands, and the sale of which in this country was subject to restrictions based on its recognition by the entire medical profession as a dangerous poison. The Society had good reason to believe that the recently elected House of Commons contained at least as large a majority of members opposed to the continuance of the opium trade as the last, and that there was not the slightest possibility of the vote of two years ago being reversed. As to the Bengal opium monopoly, the Society would urge upon his lordship that the Indian Government should be instructed still further to reduce the area of poppy cultivation for the coming season, so as to limit the production of opium to that which medical use required, and at once stop the Government opium sales at Calcutta. As regards Malwa opium, the Society submitted that the same moral grounds which could alone justify the existing prohibition of poppy culture in by far the greater portion of British India required that Her Majesty's Government should prohibit the transit of opium from the Central States through British territory to the sea, except in the case of opium prepared for medical use. With reference to the Excise system, the Society simply asked that principles which had long been recognised in the legislation of the United Kingdom be applied for the protection of our fellow subjects in India. They would urge upon his lordship to request the Indian Government without delay to prepare and adopt such regulations under the Indian Opium and Excise Acts as might be found best suited to adapt to the requirements of British India the fundamental principles that the sale of poisonous drugs was to be restricted to medical and scientific use and that discretionary powers for such sale should be entrusted only to responsible and carefully selected persons who possessed adequate knowledge of the deleterious properties of these drugs who could readily be called to account for any improper use of the discretion conferred upon them, and whose remuneration in no degree depended on the amount of their sales. In conclusion, the Society asked that the Punjab system of licensing the cultivation of the poppy should be put an end to at once.

Dr. Swanson, representing China missions, Mr. Thomas Hanbury, who described himself as an old China merchant, Mr. David McLaren of Edinburgh, the Rev. George Pearcy, representing the Wesleyan Conference, and several other members of the deputation, addressed his lordship.

Lord KIMBERLEY, in reply, thanked the deputation for the expression of their views. It was, he said, very generally agreed that opium consumption was to a certain extent an evil. That was not denied even by those who did not share the views of the deputation. The Government of India had recognised that it was their duty to restrict and regulate the consumption of opium in a manner which they certainly would not restrict and regulate the consumption of a perfectly harmless drug. Starting from that proposition, a practical question had to be dealt with. As regards the importation into China, the declaration of Sir James Fergusson was conclusive upon one point, and that was the absence of any compulsion on our part on the Chinese Government to receive opium. The Chinese Government had made a treaty under which they were allowed, very properly, to raise the duty upon opium. He had no reason to doubt that they were still of the same mind as then, and that they were extremely glad of the revenue derived from the opium. It was universally agreed that there was a very large and increasing growth of opium in China itself, and he was told, too, that there was a great improvement in the preparation of the drug in that country. His information was to the effect that now the Chinese drug was much more acceptable than in former days to those who used it. As to the action of Her Majesty's Government, he could not do better than refer to some words on this subject used recently by Mr. Gladstone. In the course of a speech, with which doubtless they were familiar, Mr. Gladstone said he was prepared, subject to the obligations of good faith, to forward any measure within the bounds of reason for limiting the Government connexion with the opium revenue and bringing that connexion, if possible, to an end. That was a proposition which

would be to a great extent agreed on by the deputation. As to the practical question which came before them, they need have no doubt as to the reception the Treasury would give to any proposal for increasing the burden upon the ratepayers of this country. The reception would be far from favourable. In calculating the loss to India they must look not only at the loss to the Government, but also to the value of the opium as exported. He could not make himself responsible for the figures, but he was told that the value of the opium might be taken at no less than thirteen millions sterling. The loss of revenue had been estimated at £3,850,000. He did not think they could rely on that estimate for the future; because he believed recent years had been exceedingly unfavourable to the production and sale of opium, and there might be a considerable increase in the future. At the same time it was quite clear that there was a tendency on the part of the opium revenue to decline. He did not regret it because it rendered the problem before them less difficult. With regard to the actual exportation, he was bound to say, as the Minister responsible for Indian affairs in this country, that the Government did not see their way—at all events, at the present time—to dispense with this large revenue. The financial position of the Indian Government at the present time was one of difficulty. As to the internal consumption, the deputation must keep in mind that he had to take into consideration all the different opinions on this subject. He thought it right to say that the strong feelings which the deputation held with regard to the extreme injury done by the consumption of opium to the people of India were not shared by a very large number of persons. Many people wholly controverted the statements constantly made that opium was a simple poison, and that no one could consume it without injury, except for medicinal purposes. On the contrary, there were those, whose opinion deserved consideration, who said that opium might be consumed by portions of the Indian people not only without injury, but with considerable benefit. The Government were at a loss how to decide the matter. He considered that opium undoubtedly did a considerable amount of mischief. How far it ought to be restricted and how far it ought to be entirely abolished were the questions before them. The Government had already taken some measures in the way of restriction, and might, as time went on, be able to do more in that direction. He hoped the deputation and those who shared their views would not dismiss lightly what the Government of India had done. He wished to separate Burmah from India in considering this question. In Upper Burmah the consumption of opium, except by the Chinese, had been prohibited, and it was extremely natural that the deputation should look to a similar prohibition being extended to Lower Burmah. The question resolved itself into one of machinery. The Government of India saw very serious practical difficulties in the way of extending the prohibition to Lower Burmah, but they had the matter under their consideration at the present time, and he was quite sure they would take any measures which they thought practicable.

A member of the deputation expressed the opinion that the exception in the case of the Chinese spoilt the effect of the prohibition in Upper Burmah.

Lord KIMBERLEY said he did not agree with that view. He could not hold out any hope that the Chinese would be deprived of their opium. It would be quite sufficient, in the first instance, to deal with the Burmese people. The position of the Government was this. They were sensible of the advisability of as much as possible restricting the consumption of opium; they had taken measures in that direction and they were quite prepared to consider further measures. Some member of the deputation had spoken of the admirable results likely to follow our showing the example of stopping the sale of a drug so deleterious as opium. He did not think the example would be very powerful if people looked to the state of things in this country. He was not himself what would be called a temperance reformer, but he was sensible of the enormous mischief done by the over-consumption of alcohol, and he would ask the deputation to consider whether we could present any very brilliant example to the Indian people while we derived a very large part of our home revenue from the consumption of alcohol, which he should think did a greater amount of harm than the consumption of opium. The views put forward by the deputation would be carefully considered, and for his part he should be extremely glad if the Government could devise means of bringing the consumption of opium within narrow limits. He should like to add one word. He desired

to impress upon the deputation that there were other drugs than opium in India, and that if opium were entirely prohibited there would be a very largely increased consumption of these drugs, which were infinitely more deleterious.

The deputation thanked Lord Kimberley for receiving them and retired.

## THE BRAIN OF THE LATE MR. GEORGE GROTE, F.R.S.

### I

In the recent number of the *Journal of Anatomy and Physiology* there is a most interesting article by the late Professor John Marshall on the brain of Mr. Grote, the eminent historian and banker, one of the founders of University College and for many years the Vice-Chancellor of the University of London. Mr. Grote died in June, 1871, of renal disease, probably of some six months' duration. His weight had fluctuated between 161 and 164 lb., his height was 5 ft. 11½ in., and he was neither very stout nor very thin. His family history was somewhat peculiar, for his paternal grandfather was a pure German who had married an Englishwoman, whilst his maternal grandfather was an Englishman who had married a French lady, but whose ancestry, however, was also partially English; so that Mr. Grote's descent was more than one-half English, one-fourth German, and less than one-fourth French. Eight years before his death this remarkable man expressed a wish in writing that his brain should be carefully weighed and examined by a skilled anatomist and any peculiarities noted, especially as to whether the cerebellum was deficient as compared with the cerebrum. The late Professor Marshall duly examined Mr. Grote's cranium and brain and his report thereon is now published. It contains not only a mine of information on the details special to Mr. Grote, but it is especially valuable for its comments and observations on the general structure of the brain and its relations to some vexed questions in cerebral physiology which are introduced into the report. In the present article, however, we must limit ourselves to the general characters and special details of Mr. Grote's brain and skull, omitting for the present some of the wider generalisations which are raised in the report. The brain, on its removal from the skull, with its covering of arachnoid and pia mater, weighed 49½ oz. avoirdupois, which is three-quarters of an ounce heavier than the average weight of the European adult brain—if we take Welcker's standard of 49 oz.—and 1½ oz. heavier than the average English adult brain of 48½ oz., as calculated by Dr. Robert Boyd from 110 observations. But Dr. Boyd's tables show conclusively that whilst the maximum weight of the brain is usually attained between thirty and forty years of age, it decreases at first slowly, then more rapidly, as age progresses, so that between seventy and eighty years of age its average weight is only 45½ oz. This would show that Mr. Grote's brain was about 3oz. above the average weight at the age at which he died. The circumference of his hat on the inside was 23½ in., and that is 1½ in. above the average of English gentlemen. But *pace* Mr. Galton, owing to individual peculiarities in the shape of the skull, the amount of hair, and the mode in which the hat is worn there may be a very wide divergence between the size of the hat and the cranium. In Mr. Grote's case this difference was 1½ in. The weight of the brain to that of the body is probably very variable, but it is generally calculated at about an average ratio of 1 in 36 to 40, but in this instance it was as low as 1 in 50, and to explain this wide difference it is suggested that it was due to the effects of the renal disease from which he died. His brain and skull showed distinct marks of atrophic changes, but those due to age cannot be separated from those due to disease. Moreover, we possess no data showing how the weight of the brain is influenced by various forms of disease, nor, as Professor Marshall points out, do we know how it is affected by stature, for Parchappe's opinion that tall persons have not only absolutely but relatively larger brains than short ones is more than doubtful. The brain weight of fifteen eminent men collected by Dr. Thurnam, when corrected for age, varies from 66 oz. in Cuvier's case to 45½ oz. in Haussman's, and Grote's position would be between the tenth and eleventh on that list. But that list

comprises men of eminence from different countries, and we have another comparison which is far more interesting. The absolute weight of the brain of Thackeray was 58½ oz., of De Morgan 52½ oz., of Grote 49½ oz., of Babbage 49½ oz., and of Professor Grant 45½ oz. When corrected for age Grote comes below Babbage and is the fourth in this series of well-known Englishmen who have recently died. Like the brains of Dupuytren and Whewell, to which it closely approximates in weight, it cannot be said to be a very large brain. Compared with Cuvier, Abercrombie and Thackeray Grote's brain seems small, but Cuvier's brain was probably abnormal, and Abercrombie's (63 oz.) surpassed the maximum weight of 60½ oz., recorded in Dr. Boyd's tables, which give the weight of 700 adult sane male brains. The relation of the weight of the cerebrum to the cerebellum was investigated after the brain had been partly hardened in spirit and its membranes removed. In this state it weighed 39 oz.; the cerebrum being 34½, the cerebellum 4, the pons varoli with the medulla oblongata ½ oz. This gives a ratio of 8.5 to 1 in Mr. Grote's case, which is about the average proportion of 8 to 1. But here considerations of height must be regarded, if we would be safe against an evident source of fallacy. From some interesting calculations on sixty-seven persons, between 5 feet 10 inches and 6 feet, thus including stature as well as age, Professor Marshall concluded that the average proportion of cerebrum to cerebellum was 7.6 to 1 at this height, whilst in Mr. Grote's case it was 8.5 to 1. No doubt it would have been very satisfactory to Mr. Grote, as it will be to his numerous friends, to have learned with scientific accuracy that in his case in proportion to the cerebrum the cerebellum was deficient; although this relative deficiency was due to an absolute increase of the cerebrum, rather than to any important diminution in the cerebellum. The consideration of the bearing of other important questions suggested by the shape of his cranium and of the cerebrum, the asymmetry of certain lobes, their relative weight, and the proportions between the grey and white matter, must be deferred to another occasion.

## FATALITIES UNDER ANÆSTHETICS.

WE have received the following notes of a death under chloroform at University College Hospital from Dr. Dudley Buxton, the anæsthetist and instructor in anæsthetics to the school.

J. G.—, a master builder, aged fifty-nine, came up from Wales to be treated for epithelioma of the jaw, involving the inside of the cheek. He was admitted under the care of Mr. Christopher Heath, who decided to remove the jaw and the tissues involved in the growth. The patient was duly prepared for the operation, and came into the room adjoining the theatre used for anæsthetising patients. He was examined and found to be free from organic disease, except the malignant growth referred to above. Chloroform was administered from folded lint which was kept a little distance from the face, the patient being supine upon a high couch table. No unusual symptoms occurred, there was a short stage of excitement, and in about five minutes the respiration was regular and even and the conjunctival reflex abolished. At this stage the couch was wheeled by dressers into the theatre, the chloroformist giving his entire attention to the patient, who appeared to be in every way in a satisfactory condition. He was then transferred to the operating table, being lifted by the four corners of sacking on which he lay from the couch table on to the operating table. The chloroformist then noticed the respiration grow shallow and at once requested Mr. Heath to pull forward the tongue. The chloroform was removed and not again reapplied and artificial respiration carefully and thoroughly carried out. In compressing the chest from below after Howard's method it was noted that the heart's action was persistent. It was observed that although the head was fully extended and the tongue was drawn out of the mouth some stridor existed as though the air passage was mechanically obstructed. Laryngotomy was performed to ensure free air entry, but a vein being unfortunately wounded gave rise to considerable venous hæmorrhage. This was probably increased by the elevation of the trunk. A Hahn's tube was inserted into the laryngotomy wound in place of the ordinary tube and the clots and blood cleared from the

mouth, and the body of the patient was placed horizontal. The tube was sucked and some blood removed by this means. The hæmorrhage was restrained by this contrivance, and oxygen was administered through the tracheal opening. Throughout these measures artificial respiration was steadily kept up, and, so far as possible, care was taken to assist the occasional sighing breaths which the patient gave. The man never resumed regular respiration, and the heart stopped within a short time of the failure of respiration. A necropsy made on the following day showed a fairly healthy heart considering the patient's age. The myocardium was firm, the aortic valves showed some thickening and the arteries were healthy. The lungs showed old pleuritic adhesions and an old cicatrix in the right apex. The bronchi contained some fluid blood, and were stained; there were no clots and certainly not enough blood to have caused much obstruction. The other viscera and nervous system were to the naked eye free from disease.

*Remarks by Dr. DUDLEY BUXTON.*—This sad case is one remarkable rather for the negative than for the positive evidence it offers whereby to arrive at the cause of death. The chloroform was from the same bottle which had been used immediately before, without let or hindrance, for two similar cases. It was given by probably the safest plan, that used by Syme and Simpson, and the respiration was watched with the utmost vigilance from start to finish. Indeed, as the respiration and colour of the patient had been so satisfactory, no regard was had to the pulse until trouble came on, when an onlooker was requested to test it. There appeared no psychic fear or dread either of the anæsthetic or of the operation; the man quietly submitted; there was no struggling, imposing undue strain on the circulatory system. The lint was kept wet with chloroform throughout and no fresh supply had been added before the dangerous symptoms arose. There was no apparent impediment, no gasping breathing, as might have led to the intake of an overdose; indeed the quiet failure of inspiration was what might be regarded as "protective" if this view of the matter be taken. The danger of forcing on chloroform into the blood was borne in mind, and until it became evident that there would be no self-elimination efforts were made rather to assist than to compel respiration. A plain statement of the above facts will probably prove more useful than spinning conjectures as to the *modus operandi* of death. It will be noted that as the above case was one in which syncope did not take place the remedies appropriate for that condition were not employed.

## ADULTERATION AND THE WORK OF THE INLAND REVENUE.

THE report by the principal of the laboratory of Somerset House, which is embodied in the thirty-fifth report of Her Majesty's Commissioners of Inland Revenue for the year ending March 31st, has recently been issued. The total number of samples analysed for the Government during the year has amounted to 48,566, which is 130 more than in the previous year, while under the twenty-second section of the Sale of Food and Drugs Act only forty-five samples have been referred by the magistrates to the Somerset House chemists for analysis. The referred samples comprised butter, buttermilk, coffee, dandelion coffee, lard, linseed meal, milk, mustard, whisky, white pepper and rum. As is nearly always the case, the larger proportion of the samples consisted of milk. Of these, four were alleged to have been diluted with water and deprived of part of their fat, but only in one of the cases, however, could the referees support the charge, and that only in respect of abstraction of fat. In the case of twenty-five other samples they concurred in the conclusions of the local analyst in respect to twenty-one of them. The remaining four afforded no evidence of dilution, but the milk in each instance had undoubtedly been deprived of part of its fat, although this offence had not been charged.

It is noteworthy that the Somerset House authorities confirmed the analyses of the local analyst in twenty-one out of twenty-five cases of milk in which the charge was dilution with water. Doubtless the results of analysis of the four samples to which exception was taken were the same, but

probably the interpretation of these results led to a different conclusion respecting the quality of the milk. In order to determine whether a milk is pure or not it is obviously necessary to adopt a standard of quality from which all other samples may be judged. Unless this standard is agreed upon once for all, differences of opinion as to whether a milk has been diluted or not are bound to exist. But the difficulty lies in fixing a standard of quality for an article which, like milk, varies so widely in composition. If a high limit is adopted then, no doubt, in a few solitary instances milk vendors would be dealt with unfairly. If, on the contrary, the limit adopted be low, then probably the majority of milk dealers would be enabled to water to a certain extent the milk of average yield. According to a large number of analyses published in 1883 by the principal of the laboratory at Somerset House, Dr. Bell, the non-fatty solids of milk from individual cows vary from 8.0 to 11.27 per cent., and the fat from 1.92 to 6.87 per cent.; while in the case of dairy samples the non-fatty solids vary from 8.5 to 9.91 per cent. and the fat from 2.90 to 5.1 per cent. Occasionally a milk falls below even 8.5 per cent. in non-fatty matters and 1.9 in fat, which must still be regarded as genuine, the samples having been drawn in the presence of a responsible person. There is reason to believe, however, that when a standard as low as 8.5 is taken the milk vendor is treated very leniently—in the majority of instances probably too leniently; and it is useless for the public to expect to be provided with—inasmuch as the Act does not encourage the supply of—milk of really excellent and irreproachable quality. The same holds true in regard to fat. If the limit of genuine milk is to be 2 per cent., then obviously the dealer may with impunity skim down a milk containing 5 per cent. to the extent of 3 per cent. As things stand, in fact, the Act does not sufficiently protect the public, who according to its present reading may be provided with milk that is "genuine" compared with the low standard, but to which it is pretty certain water has been added, and from which cream has been abstracted. The report referred to, however, gives some hope of this matter being placed upon a more satisfactory basis. Dr. Bell has considered it desirable, inasmuch as the quality of milk is materially affected by the breed of cows and by the food they receive, to make a fresh investigation into the character of the milk now generally produced in order to ascertain whether any material changes have taken place, after an interval of ten years, in its composition which would affect the standards of quality hitherto relied on as a guide in dealing with samples suspected to have been tampered with. This investigation will be continued during the present year, so far as may be consistent with the current work of the department. That the Somerset House authorities have hitherto adopted a low limit, both as regards milk and butter, is quite obvious from a consideration of the cases appearing at the police-courts from time to time. The local analyst reports adulteration—it may be to a slight extent only—and the referees—although they should, of course, obtain the same analytical figures, everything else being the same—are, in many instances, unable to affirm that the sample is sophisticated. This frequently happens, and the competency of the local analyst is not unnaturally brought into question; but it must be admitted that in the case of milk the analysis of the local analyst is more likely to indicate correctly its character than is the analysis of the Somerset House authorities. The local analyst examines the milk before any important change in its composition has taken place, whereas the referees unavoidably examine the sample when it is several days old, and consequently when it has undergone considerable decomposition. With regard to the standard quality of milk there really seems no reason why it should not be subjected to the same regulation as spirits—i.e., never to be allowed to contain more than a certain and reasonable proportion of water. It should, so to speak, be kept up to strength. It must be remembered that milk is not only an essential article of diet, but is also one used largely for infants and invalids, to whom the abstraction of food elements is a serious matter. Apart from this, the quality of the water used by the dishonest tradesman to dilute the milk may not be above suspicion. It is for the owner to see that the cow is not ill fed, while if it is in an unhealthy condition the milk from it should not be sold at all. The rich milk of some cows could be mixed with the poor milk of others and so an average product obtained which would come well within the limits of a milk of really good quality.

Amongst the investigations carried out by the Somerset

House laboratory officials in other departments the result of an inquiry into the value of disinfectants for the Board of Trade calls for notice. The work of the committee appointed by the Board was undertaken to fix a standard of efficiency for disinfectants intended to be used on board passenger and merchant ships, and to revise the list of disinfectants in the medical scales of the Board of Trade. It was decided to adopt as standards a solution containing 80 per cent. carbolic acid and a powder containing 20 per cent. of the acid. Every disinfectant on the Board of Trade list was examined bacteriologically, in order to determine whether it was equal in value to the standard as an antiseptic and disinfectant. The experiments extended over several months, the result being that nearly every liquid disinfectant on the list was found to be inferior to an equal bulk of the carbolic acid solution, and in the case of powders to an equal weight of the carbolic acid powder. The method adopted is not explained, and the kind of organism experimented upon is not mentioned; but it must be admitted that the conclusions come to by the committee are not in agreement with the observations of previous investigators, such as Koch, Martens, Bucholtz and others.

Further on in the report a very satisfactory account is given of the home manufacture of tobacco. It is carried on with almost absolute freedom from adulteration, and the regulations as to restriction of water have been so satisfactorily observed during the year that it has only been necessary in two cases to take proceedings against manufacturers.

The evils attending the drinking of methylated spirit and the frauds thus committed against the revenue have received due attention. Within a limited area in the north of Ireland, it will be remembered, methylated spirit was being used as a beverage by some of the rural population, so the Revenue decided, at the suggestion of Dr. Bell, that while methylated spirit for general use in the arts and manufactures should be still allowed as hitherto, that portion sold by retail to the general public should contain a small addition of petroleum. This admixture renders the methylated spirit turbid when diluted, and also more offensive in character; and from the accounts from the district principally affected the retail sales since its introduction have largely fallen off, and there is every reason to believe that the practice of using such spirit for drinking purposes has been extensively abandoned, if not altogether stamped out.

### FELIXSTOWE SPA.

By H. MACNAUGHTON JONES, M.D., F.R.C.S.I. & ED., &c.

IT may interest readers of THE LANCET to know something of Felixstowe and its medicinal spa. Not that I assume that many who have sent patients to imbibe the invigorating and delightful air of the Suffolk coast and the breezes which blow over Felixstowe, Aldeburgh and Lowestoft have not themselves enjoyed the bracing effects of the sea air of these well-known watering-places, each of which has its own special attractions for different visitors; but there are several who have not had the opportunity of visiting these Suffolk health resorts, and for whom a few notes of one of them and its natural mineral spring may be of interest. Facing the German Ocean, between Harwich on the south and Bawdsey at the mouth of the Deben river on the north, Felixstowe beach occupies an amphitheatre which has at one point of the crescent Landguard Fort, commanding the entrance to Harwich, and at the other a picturesque villa perched just above the cliffs of red crag and London clay that bound this part of the coast and over which there is a delightful walk to Felixstowe ferry. In the distance to the south can be seen the long head of Walton-on-the-Naze, and from certain vantage-points in the neighbourhood can be obtained good views of Harwich harbour and shipping and the lighthouse of the quiet little bathing town of Dovercourt. The lights of the *Cork* and the *Sunk* flash right in front of the beach some three and twelve miles off respectively, and a pleasant hour can be spent on board the former lightship after an agreeable row of some three-quarters of an hour from Felixstowe. In 1105 a priory of black monks was founded and dedicated to St. Felix; here the renowned bishop had resided, and there are many evidences that Roman, Saxon and Norman settlers successively lived here, the latter conquerors leaving in the remains of Walton Castle, distributed in pond and ancient church, clear proofs of their military

resources. The temporary sojourn of the Empress of Germany at Felixstowe in 1891 brought this quiet watering-place into still greater prominence as a summer seaside resort; and the famous golf grounds and the well-known golfing club—the links of which are splendidly placed on the side of the Deben river, close to the sea, about two miles from the eastern side of the town—attract many visitors. The capital bathing beach and the safe sands render Felixstowe a typical place for children, and each year it is growing more in popular favour as a children's holiday resort. Some few years since Dr. J. E. Taylor wrote a report in connexion with a scheme for the construction of a waterworks for Felixstowe, and in the necessary examination of the well water he found that it contained many valuable mineral ingredients, and amongst these iron; and Dr. Frankland, who had specimens of the water submitted to him for report as to its suitability for domestic use, while proving that this was impossible, suggested that it might be usefully employed for medicinal purposes. As in other chalybeate springs, the iron exists in association with sulphur in the pyrites which occurs in the London clay at Felixstowe. Dr. Taylor then pointed out that there was a trace of phosphates in the water, and accounted for its presence through the coprolites or phosphatic nodules found at the base of the red crag at Felixstowe. It does not appear from Dr. Frankland's analysis (made in 1891) of the well water that he found any phosphates in it. Dr. Taylor, having tested personally and with others the medicinal properties of the spa, was induced to try its aeration by artificial means, hoping thus to get rid of the smell and unpleasant taste due to the decomposition of the pyrites which, as I have said, is found in the London clay of the soil. In this he has been most successful. The taste reminds one of the Wienbrunnen spring at Schwabach—sparkling and mildly chalybeate. I have spoken to several people of various ages who have taken the water as a chalybeate tonic, and on whom it has had a good effect. The recent analysis (1891) of Dr. Frankland is as follows.

“One thousand parts of the water yielded the following ingredients:—

	Parts.
Total solid residue dried at 130° C. ... ..	85.30
Lime as carbonate (CaCO <sub>3</sub> ) ... ..	11.76
Magnesia as carbonate (MgCO <sub>3</sub> ) ... ..	2.16
Total magnesia as carbonate (MgO) ... ..	5.78
Soda (ONa <sub>2</sub> ) ... ..	22.25
Potash (OK <sub>2</sub> ) ... ..	1.21
Chlorine ... ..	30.44
Sulphuric anhydride (SO <sub>3</sub> ) ... ..	3.40
Silica ... ..	1.51
Alumina and peroxide of iron (Al <sub>2</sub> O <sub>3</sub> & Fe <sub>2</sub> O <sub>3</sub> ) ... ..	0.11
Organic carbon ... ..	0.063
Organic nitrogen ... ..	0.019
Ammonia (NH <sub>3</sub> ) ... ..	0.070
Nitrogen as nitrates ... ..	0.0
Phosphoric acid ... ..	0.0

These constituents are probably combined in the water in the following manner:—

	Parts.
Carbonate of lime (CaCO <sub>3</sub> ) ... ..	21.00
Carbonate of magnesia (MgCO <sub>3</sub> ) ... ..	4.54
Sulphate of lime (CaSO <sub>4</sub> ) ... ..	4.01
Sulphate of magnesia (MgSO <sub>4</sub> ) ... ..	1.52
Chloride of magnesium (MgCl <sub>2</sub> ) ... ..	7.36
Chloride of sodium (NaCl) ... ..	39.60
Chloride of potassium (KCl) ... ..	1.92
Silicate of sodium (SiNa <sub>2</sub> O <sub>3</sub> ) ... ..	3.07
Alumina and peroxide of iron (Al <sub>2</sub> O <sub>3</sub> & Fe <sub>2</sub> O <sub>3</sub> ) ... ..	0.11

The aerated spa water was pleasant to the taste and well charged with carbonic acid.”

The constitution of such a water would justify the belief that it must prove of use in cases of atonic dyspepsia, and as a mild purgative from the sulphate and chloride of magnesia which it contains; both used internally and as a bath, such a spa should prove of efficacy in gouty rheumatism and muscular neuralgias. A spring which can yield an unlimited supply within a few yards of the beach of one of the most salubrious of our sea-coast resorts, in a neighbourhood with a singularly dry climate and a soil that quickly absorbs moisture, free of moist exhalations, and that by its situation is protected from the severity of the east winds, that are broken by the points of the crescent to which I have already referred, is well worth developing. The drinking water of Felixstowe is singularly pure, being drawn from an

artesian well which is sunk in the chalk. There are plenty of good apartments, charmingly situated villas, and an excellent hotel, which is beautifully situated and within a few hundred yards of the spa. There are pleasant drives in the vicinity, and within an hour and a half's driving distance is the magnificent mansion of Captain Pretymann, situated in one of the most beautiful parks in England; here the visitor may feast his eyes on some of the choicest specimens of Gainsborough, Caravacci, Vandyke, Koek-Koek, Stansfield, and the marvellous masterpiece of Murillo, the Pool of Bethesda (for which, it is said, £20,000 was offered by the Spanish Government and refused), as well as many other works of art, besides figures and busts by eminent sculptors, placed here by the late Colonel Tomline, who was the previous owner of Orwell Park. I may, in passing, mention that a most delightful excursion can be made from Ipswich to Felixstowe, or *vice versa*, on the Orwell river, or an invigorating and pleasant sail can be had up the Deben to Woodbridge. But my purpose is mainly to draw attention to the medicinal properties of the Felixstowe Spa as a matter well worth remembering by those who may not happen to know of it and who send patients to this pretty watering town on the Suffolk coast. Felixstowe is justly proud of its neat, well-kept and splendidly situated "Suffolk Convalescent Home." One thing only I would add in conclusion, that to render Felixstowe as attractive as its natural advantages claim for it, those in authority or the local magnates should see that its resources for recreation and public enjoyment are attended to, and that the value of its mineral spring is made more apparent by attention to what is called the "Spa House," but which might easily be converted into a neat kursaal, and thus the attention of visitors be drawn to what undoubtedly is a characteristic feature of this charming little town.

Harley-street, W.

## THE ANNUAL REPORT OF THE VETERINARY DEPARTMENT OF THE BOARD OF AGRICULTURE.

THE health and prosperity of the live stock of the United Kingdom is of so much importance to the community that the Annual Report of the Board of Agriculture, which deals more especially with some of the contagious diseases of the domestic animals, must always possess a considerable amount of interest for those whose function it is to attend to the sanitary condition and disorders of man. The report for 1891, which has only now, in the last quarter of 1892, been issued, and which has no information with regard to the health of animals in Ireland, is so far satisfactory in that it contains evidence of a diminution in the prevalence of the contagious pleuro-pneumonia of cattle, which has caused almost incalculable damage since its introduction half a century ago, and gives us reasonable grounds for looking forward to its extinction at no distant date. It is stated that during the year the attention of the Department was concentrated on the administration of the Pleuro-pneumonia Act of 1890 in all parts of the country where the disease was discovered. The endeavour to check the disease has not only been attended with heavy cost to the nation, as whole herds have been killed and farms and dairies cleared out, compensation for this destruction being made from the Treasury, but large tracts of country have been placed under severe restrictions in regard to the sale and movement of cattle. This has seriously hampered trade and inflicted grave loss and inconvenience on the owners of cattle. Of course it was to be expected that such drastic measures, which looked like "making a desert and calling it peace," would raise up considerable opposition, as they meant something like ruin to many of those concerned in their operation. But this opposition was little regarded, and it is satisfactory to learn that "the success which has attended the procedure furnishes the justification of the severity of the regulations which it was deemed expedient to enforce in certain scheduled districts while the rest of the country was left quite free from restrictions." From the returns of the cattle slaughtered by order of the Board it would appear that 72·3 per cent. of the diseased animals were cows or heifers, only 1·3 per cent. being bulls. This difference can be explained by the fact

that not only is there a great preponderance of cows over bulls, but that the former, as dairy cows, are exposed to influences favourable to the extension of contagious diseases. As the report has it, "pleuro-pneumonia cannot be caused by insanitary surroundings; but when disease has been introduced among a herd by the agency of a living diseased animal the close association of a number of cows in a badly ventilated shed must favour the spreading of the disorder. Besides which, it is at least probable that the artificial conditions under which cows are kept have led to the development of a predisposition which renders them specially susceptible to the malady. At any rate, there is good evidence that the popular idea of the shed cow being the chief source of danger is not without justification." There is reference to some experiments with the meat and milk of tuberculous cattle, but we cannot see that they add much, if anything, to the knowledge acquired long ago. For instance, one of the results arrived at is that thorough cooking is effectual in destroying the activity of tubercle virus, which, we fancy, no one ever doubted. In this connexion we have good authority for stating that in another three or four months' time the promised report on Tuberculosis by the Royal Commission will be forthcoming. The wholesale slaughter of cattle for contagious pleuro-pneumonia has revealed the extent to which the far more serious scourge of bovine tuberculosis prevails in Great Britain. Of the total cattle slaughtered because of being affected with pleuro-pneumonia or having been exposed to infection, 12·22 per cent. were found to be more or less tuberculous; of the cows and heifers in milk or in calf, 16·9 per cent. were tuberculous; of bulls, 1·53 per cent. were thus affected; of other cattle over one year old, 1·2 per cent. were also diseased, as were 1·2 per cent. under one year old. In Midlothian, of the cows slaughtered 22·5 per cent. were tuberculous, and of those in and around London, 15·53 per cent. were in the same state. Anthrax prevailed in fifty counties in Great Britain, the outbreaks amounting to 226, in which 471 animals were attacked, exclusive of horses; but as the Department believes that this dangerous disease cannot be eradicated by repressive measures, nothing is done in the way of introducing measures for the protection of animals on infected lands, such as Pasteurian inoculation, which has proved so satisfactory in France and some other countries. Swine fever, a very fatal and highly contagious and infectious disease of the porcine tribe, prevailed unchecked by the regulations now in force, as the application of these is left to the option of the local authorities, who, of course, are worse than useless in dealing with this class of maladies. Allusion is made to the losses among animals during transit by sea, from which it appears that in cargoes sent from the United States, Canada, and the Argentine Republic 5971 cattle and 2665 sheep perished at sea, 323 cattle and 107 sheep were landed dead, and 471 cattle and 113 sheep were so injured as to necessitate slaughter being resorted to at the port of landing.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6514 births and 3837 deaths were registered during the week ending Nov. 5th. The annual rate of mortality in these towns, which had increased from 17·3 to 19·5 per 1000 in the preceding three weeks, further rose to 19·6 last week. In London the rate was 18·2 per 1000, while it averaged 20·6 in the thirty-two provincial towns. The lowest rates in these towns were 11·3 in Swansea, 14·1 in Derby, 15·1 in Leicester and in Cardiff, and 15·5 in Halifax; the highest rates were 25·7 in Manchester, 26·0 in Blackburn, 26·8 in Wolverhampton, 26·9 in Bolton, and 30·3 in Salford. The 3837 deaths included 434 which were referred to the principal zymotic diseases, against 387 and 406 in the preceding two weeks; of these, 130 resulted from measles, 78 from diarrhoea, 75 from scarlet fever, 70 from diphtheria, 40 from whooping-cough, 40 from "fever" (principally enteric), and one from small-pox. No fatal case of any of these diseases occurred last week in Derby and in Burnley; in the other towns they caused the lowest death-rates in Halifax, Swansea and Newcastle-upon-Tyne, and the highest rates in West Ham, Croydon, Brighton, Hull, and Salford. The greatest mortality from measles occurred in Brighton, Cardiff, Oldham, West Ham, Hull and Salford; from scarlet fever in Preston and Plymouth; from "fever"

in Preston and Birkenhead; and from diarrhoea in Blackburn, Hull and Wolverhampton. The mortality from whooping-cough showed no marked excess in any of the large towns. The 70 deaths from diphtheria included 47 in London, 6 in Croydon and 3 in Brighton. A fatal case of small-pox was registered in Leeds, but not one in London or in any other of the thirty-three large towns; 4 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 1 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 4067, against 3797, 3936 and 4012 on the preceding three Saturdays; 462 new cases were admitted during the week, against 484 and 410 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 295 in the preceding nine weeks, further rose last week to 319, but were 74 below the corrected average. The causes of 79, or 2·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Bolton, Sunderland, Newcastle-upon-Tyne, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Balckburn, and Gateshead.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the largest Scotch towns, which had increased from 18·1 to 21·3 per 1000 in the preceding three weeks, further rose to 22·9 during the week ending Nov. 5th, and exceeded by 3·3 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·8 in Paisley and 17·4 in Dundee to 25·3 in Leith and 26·1 in Edinburgh and in Aberdeen. The 637 deaths in these towns included 69 which were referred to measles, 13 to scarlet fever, 10 to diphtheria, 6 to diarrhoea, 5 to whooping-cough, 5 to "fever," and not one to small-pox. In all, 108 deaths resulted from these principal zymotic diseases, against 87 and 80 in the preceding two weeks. These 108 deaths were equal to an annual rate of 3·9 per 1000, which exceeded by 1·7 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 12 to 43 in the preceding six weeks, further rose last week to 69, of which 34 occurred in Edinburgh, 17 in Aberdeen, and 1 in Leith. The deaths referred to scarlet fever, which had declined from 16 to 14 in the preceding three weeks, further fell to 13 last week, and included 9 in Glasgow and 2 in Leith. The 10 fatal cases of diphtheria were within 2 of 5 in the preceding week, and included 6 in Glasgow and 3 in Aberdeen. The deaths from whooping-cough, which had been 10 in each of the previous two weeks, declined to 5 last week, all of which occurred in Glasgow. The 5 fatal cases of "fever" exceeded the number recorded in any recent week, and included 3 in Leith and 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 80 to 138 in the preceding three weeks, further rose to 142 last week, but were 68 below the number in the corresponding week of last year. The causes of 78, or more than 12 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·4 and 25·8 per 1000 in the preceding two weeks, further rose to 28·5 during the week ending Nov. 5th. During the first five weeks of the current quarter the death-rate in the city averaged 23·9 per 1000, against 17·6 in London and 21·7 in Edinburgh. The 191 deaths in Dublin during the week under notice included 10 which were referred to different forms of "fever," 3 to scarlet fever, and not one either to small-pox, measles, diphtheria, whooping-cough, or diarrhoea. In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 2·0 in London and 7·3 in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 6 in the preceding two weeks, further rose to 10 during the week under notice, a higher number than in any week since December last. The 3 fatal cases of scarlet fever exceeded those recorded in any week since February, 1889. The 191 deaths registered in Dublin last week included 35 of infants

under one year of age and 43 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in any recent week. Four inquest cases and 4 deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of 20, or more than 10 per cent., of the deaths in the city last week were not certified.

#### VITAL STATISTICS OF LONDON DURING OCTOBER, 1892.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during the month of October in each of the forty-one sanitary districts of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 17·9 per 1000 of the population, estimated at 4,263,294 persons in the middle of this year. Owing to the continued epidemic prevalence of scarlet fever and of diphtheria in London this rate shows a slight further increase upon those recorded in the preceding eight months, which had continuously risen from 5·1 to 17·4 per 1000. Among the various sanitary districts the rates last month were considerably below the average in Kensington, Westminster, St. James Westminster, Marylebone, Strand, St. Olave Southwark, and Lewisham (excluding Penge); while they showed the largest excess in Hackney, Holborn, Shoreditch, Bethnal Green, Mile-end Old Town, and Poplar. The prevalence of small-pox in London showed an increase during October, 10 cases being notified during the month, against 3 in September; of these 10 cases 3 belonged to St. Pancras and 2 to Paddington sanitary districts. The Metropolitan Asylum Hospitals and the Highgate Small-pox Hospital contained 6 small-pox patients at the end of October, against 8 at the end of each of the preceding two months; the weekly admissions averaged one only, against 2 in each of the previous two months. The prevalence of scarlet fever in London during October showed a slight further increase upon that recorded in recent months; this disease was proportionally most prevalent in Hackney, Holborn, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, and Bermondsey sanitary districts. The Metropolitan Asylum Hospitals contained 3843 scarlet fever patients at the end of October, against numbers increasing from 1142 to 3407 at the end of the preceding eight months; the weekly admissions averaged 429, against 335, 378, and 355 in the preceding three months. Diphtheria also showed slightly increased prevalence during the month under notice; this disease was proportionally most prevalent in Islington, Hackney, City of London, Bethnal Green, Poplar, St. Saviour Southwark, and Lewisham sanitary districts. There were 312 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of October, against numbers steadily increasing from 198 to 318 at the end of the preceding seven months; the weekly admissions averaged 57, against 56, 55 and 54 in the preceding three months. Enteric fever was proportionally most prevalent in Islington, Hackney, St. Giles, and Mile End Old Town sanitary districts. The Metropolitan Asylum Hospitals contained 124 enteric fever patients at the end of October, against numbers increasing from 47 to 113 at the end of the preceding five months; the weekly admissions averaged 15, against 14 and 20 in the preceding two months. Erysipelas showed the highest proportional prevalence during the month under notice in Holborn, Clerkenwell, St. Luke, Bethnal Green, Whitechapel, and St. George-in-the-East sanitary districts. Six cases of puerperal fever were notified during October in Islington and 4 in St. Pancras sanitary districts.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed among the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the four weeks ending on Saturday, Oct. 29th, the deaths of 5600 persons belonging to London were registered, equal to an annual rate of 17·1 per 1000, against 17·8, 16·9, and 15·7 in the preceding three months. The lowest death-rates during October in the various sanitary districts were 11·3 in Hampstead, 12·4 in Plumstead, 12·7 in Battersea, 12·9 in Lewisham (excluding Penge), 13·0 in Kensington, and 13·2 in Wandsworth; in the other

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON.—OCTOBER, 1892.  
(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1892.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths from all causes.	Deaths per 1000 living.	Deaths of infants under one year to 1000 births.

\* Including 47 cases notified as "meningococcus group."

sanitary districts the rates ranged upwards to 23·2 in St. Saviour Southwark, 23·9 in Whitechapel, 26·1 in Holborn, 26·6 in St. George Southwark, 28·2 in St. George-in-the-East, 28·5 in St. Olave Southwark, and 30·3 in St. Martin-in-the-Fields. During the four weeks of October 610 deaths were referred to the principal zymotic diseases in London; of these, 194 resulted from diphtheria, 125 from diarrhoea, 124 from scarlet fever, 86 from measles, 56 from different forms of "fever" (including 55 from enteric fever and 1 from an ill-defined fever), 25 from whooping-cough, and not one from small-pox. These 610 deaths were equal to an annual rate of 1·9 per 1000, against 3·9, 3·4, and 2·6 in the preceding three months. Among the various sanitary districts the lowest zymotic death-rates were recorded in Chelsea, Westminster, Hampstead, St. Giles, Strand, Rotherhithe, and Battersea; and the highest rates in St. Martin-in-the-Fields, Holborn, Bethnal Green, St. George-in-the-East, St. Saviour Southwark, St. George Southwark, and Woolwich. The 86 deaths referred to measles were 35 below the corrected average number in the corresponding month of the preceding ten years; among the various sanitary districts this disease showed the highest proportional fatality in St. George-in-the-East, Bethnal Green, St. George Southwark, and Camberwell. The 124 deaths from scarlet fever were 20 below the corrected average, notwithstanding its epidemic prevalence; this disease was proportionally most fatal in Hackney, St. Martin-in-the-Fields, Bethnal Green, St. George-in-the-East, and Lewisham. The 194 fatal cases of diphtheria were no less than 84 above the corrected average; this disease showed the highest proportional fatality in Hackney, St. Martin-in-the-Fields, Clerkenwell, St. George-in-the-East, Limehouse, Mile End Old Town, St. Saviour Southwark, Lewisham and Plumstead. The 20 deaths referred to whooping-cough were little more than one-fourth of the corrected average; this disease showed no marked fatality in any of the sanitary districts. The 56 deaths referred to different forms of "fever" were 29 below the corrected average; there was no marked excess of fever mortality in any of the sanitary districts during the month under notice. The 125 fatal cases of diarrhoea were 52 below the corrected average. In conclusion, it may be stated that the mortality in London during October from these principal zymotic diseases was as much as 18 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 137 per 1000 during October, and was slightly below the average; the lowest rates of infant mortality were recorded in Hammersmith, St. James Westminster, Marylebone, St. Luke, City of London, Rotherhithe, and Plumstead; the highest rates in Chelsea, Strand, Holborn, St. George-in-the-East, Mile End Old Town, St. Saviour Southwark, St. George Southwark, and Camberwell.

## THE SERVICES.

### MOVEMENTS OF MEDICAL STAFF.

**SURGEON-COLONEL P. BURKE SMITH** has been transferred from Woolwich to Netley, where he has assumed the duties of Principal Medical Officer in succession to Surgeon-Major-General Hinde, retired. The following officers have arrived home from India on completion of a tour of service:—Surgeon-Major Lane, Surgeon-Captains Hayman and Philson. Surgeon-Captain Lavie has come home on sick leave. Surgeon-Captain Cottell has embarked for Gibraltar on a tour of foreign service. Surgeon-Captain Robinson has been transferred to Fleetwood, Surgeon-Captain Macleod to Canterbury, and Surgeon-Captain Meek to Newry. Surgeon-Major Fox has been transferred from Ballincollig to Cork.

### ARMY MEDICAL STAFF.

Surgeon-Lieutenant W. J. Smyth, M.D., A.M.S., has been attached to the Grenadier Guards. Surgeon-Major-General George Langford Hinde, C.B., has been placed on retired pay. Surgeon-Lieutenant-Colonel William F. Burnett has been promoted to Brigade-Surgeon-Lieutenant-Colonel.

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant John Michael Harding Martin, M.D., F.R.C.S. Eng., 1st Volunteer Battalion, the East Lancashire Regiment, has been made a Surgeon-Lieutenant.

### INDIAN MEDICAL SERVICE.

The following appointments have been made:—Surgeon-

Lieutenant-Colonel F. Lyons, M.S., has been appointed a member of the Poona Standing Medical Board. Surgeon-Major A. Peterkin, Medical Staff, has been appointed to the Medical Charge of the Station Hospital, Indore. Brigade-Surgeon-Lieutenant-Colonel R. P. Ferguson has been appointed Administrative Medical Officer in the Bengal Command (Allahabad District). Surgeon-Captains A. F. Ferguson, M.B., K. H. Mistri, G. E. Fooks, and J. W. T. Anderson, F.R.C.S., having completed twelve years' service, to be Surgeon-Major from the date specified, subject to Her Majesty's approval. The following transfers have been made: Surgeon-Captain W. H. Bean, Army Medical Staff, has been posted for duty to the Madras District. The services of Surgeon-Captain A. V. Anderson, M.B., I.M.S., have been placed at the disposal of Government for employment in the Civil Department. Surgeon-Lieutenant P. C. Gabbett, Indian Medical Service, has been posted for duty to the Madras District, and Surgeon-Lieutenant J. L. Macrae, Indian Medical Service, to the Secunderabad District. Brigade-Surgeon-Lieutenant-Colonel W. Gray, I.M.S., arrived at Bombay on the 17th inst. from six months' leave in England. Surgeon-Major-General William Frederick de Fabeck, M.D., I.M.S., Surgeon-General with the Government of Madras, has been granted a good service pension.

### NAVAL MEDICAL SERVICE.

Appointments: Fleet Surgeon John Lyon, M.D., to the *Impregnable*. Staff Surgeons: Thomas E. H. Williams to the *Pelican* and George F. Wales to the *Beagle*. Surgeons: Robert Hickson to Bermuda Hospital; Octavius S. Fisher to the *Alacrity*; John Lowney to the *Itadpole*; Ernest E. P. Tindall to the *Plover*; E. C. Lomas, M.D., to the *Pigmy*; John Dowson to the *Pembroke*; Bowen S. Mends, R.M.A. Division, Portsmouth; Anthony Kidd to the *Caroline*; Ernest E. Bray to the *Mercury*; Edward G. Swan to the *Archer*; Frederick W. Parker to the *Cambridge*; and Ernest A. Shaw, B.A., M.B., to the *Hearty*.

### YEOMANRY CAVALRY.

Herts: William Carus Brendon Revill, Gent., has been promoted to Veterinary-Lieutenant.

### VOLUNTEERS.

1st Essex (Eastern Division Royal Artillery): Surgeon-Lieutenant F. W. D. McGachen has resigned his commission. Rifle: 4th Volunteer Battalion, the King's (Liverpool Regiment): Surgeon-Captain W. J. Fleetwood, M.D., has been promoted to Surgeon-Major.

### THE FRENCH IN DAHOMEY.

According to telegrams, the French losses from casualties in Colonel Dodd's column during the campaign amount to a total of 151, to which must be added, however, the number of those who died from illness on the march from Kotonou to Dakar. There seems to have been a good deal of sharp fighting, especially of late, the official details of which have not yet been promulgated. The *Figaro* publishes some intelligence received from private sources—which is probably of an exaggerated character—as to the very large amount of sickness that exists in the French force. The climate is described as most trying and the inefficiency from fever and sickness of various kinds is alleged to amount to one-fifth of the force. It may be interesting to recall our own military experiences on the Gold Coast. The climate is no doubt a bad one at all times, although it is much less unhealthy during the limited dry season. The wet seasons, of which there are two—from March to May and from August to October—are the most unhealthy. The dry months—from December to March—comprise the healthy season. Malarious fevers and dysentery are the more important diseases. Previously to the Ashanti campaign of 1873-74 the results of our military expeditions in that country were unfortunate, to say the least, if not calamitous as regards the health of the troops employed. A detachment of white soldiers of the Royal African Regiment serving at Cape Coast lost upwards of 90 per cent. of their strength in 1824. The expedition in 1864, designed to undertake the same operations that were subsequently carried out under Sir Garnet Wolseley, suffered from an appalling amount of sickness, and the Royal Marines, stationed on the Gold Coast just prior to the Ashanti expedition, lost eighteen men out of 104; whereas there were only eighty-one deaths from disease and wounds among the 2587 European officers and men composing the force that advanced to Coomassie. The difference in these results was no doubt attributable to the healthy dry season having been selected as the time for the

expedition and to the extreme care taken to provide for all its sanitary requirements.

#### WATER FAMINE IN TRINIDAD.

The water famine under which the population—amounting to some 40,000 persons—of Trinidad, the principal town at the port of Spain, were suffering in 1891 is alleged to be still present, nothing in the way of remedy having been yet attempted. The matter has been already discussed in the House of Commons, and the late Under-Secretary for the Colonies promised to look into it. It is said that a state of things exists which is simply incredible; that the majority of the householders are without sufficient water for drinking and cooking purposes, to say nothing of ablution and drainage requirements. At the same time it is declared that an almost inexhaustible supply could be obtained from the hills at the back of the town by the expenditure of a few thousand pounds; if so, we cannot exactly understand why the townspeople do not set about organising some practical engineering scheme for utilising this water-supply. With a population of 40,000 it would seem to be possible to carry out locally a public work of such an absolutely essential kind. Are the aid and sanction of the home Government necessary for the purpose? Time was when troops were stationed at Trinidad, but we believe that there are none quartered there at present.

#### SANITATION IN BENGAL.

An amended Bengal Municipal Bill has been drafted which is likely to prove a very useful measure in the powers it confers upon the Lieutenant-Governor and the municipalities and district boards to enforce sanitation and drainage and establish wholesome water-supplies. The *Pioneer* of the 20th ult. shortly describes the various clauses of the new Bill, and very prudently urges that as measures for sanitation and public works mean the outlay of money they require to be gradually introduced and carried out, otherwise the municipal and district authorities will be rescued from the Scylla of insanitation only to be landed in the Charybdis of bankruptcy. We are very glad, however, to notice that the people and local native authorities of the different districts in Bengal seem to be alive to the necessity of doing what they can towards carrying out sanitary improvements.

#### THE DEATH OF LIEUT. HUDDLESTON, R.E.

The inquest on this officer, whose death at Chatham was attributed to his having been poisoned by eating tinned sardines or caviare, has been adjourned. The Home Office has directed Dr. Stevenson of Guy's Hospital to analyse the contents of the stomach and the suspected sardines and caviare.

#### ASSISTANCE FOR CIVIL SURGEONS.

The heads of the Madras Medical Department have made strong representations to the government respecting the lack of surgeons available for civil duty, obliging them to place assistant-surgeons in charge of districts with the inspection of large institutions; and the superintendence of a considerable staff, while there is absolutely no reserve. The authorities recognise the gravity of the position and they ask for a report as to whether the services of local doctors might not be retained.

#### PERMANENT REST CAMP.

The *Madras Mail* is glad to learn that a permanent Rest Camp for British troops is likely to be formed before long at Madras. Great hardships were experienced by European details last year owing to there being no such camp. An excellent site for the camp, facing the sea and close to the Fort, has been selected.

We have to announce with regret the death of Staff-Surgeon William Dickson Smyth, M.D. R.N., (retired) who died in his 57th year at his residence at St. Leonards and of Surg.-Major T. M. Lownds, M.D. (retired, Bombay Army) who died at Wateringbury, Kent, aged 64.

**PRESENTATION.**—On Thursday, Oct. 13th, Mr. H. Lewis-Hughes, L.R.C.P. and S. Edin., lecturer to the St. John ambulance class, Dowlais, was presented, in recognition of his services as ambulance instructor during the summer months, with a Morton's ophthalmoscope, bearing the inscription: "Presented to Dr. H. Lewis-Hughes by the Railway and Police Ambulance Class, Dowlais, Oct. 13th, 1892."

## Correspondence.

"Audi alteram partem."

### "MEDICAL CERTIFICATES AND DEATH REGISTRATION."

To the Editors of THE LANCET.

SIRS,—With reference to your leading article in THE LANCET of Nov. 5th I would suggest that efforts should be made to obtain such an amendment of the Births and Deaths Registration Act of 1874 as shall bring it into harmony with the Coroners Act of 1887 and relieve medical practitioners from much worry, anxiety and responsibility. The profession must take some blame to itself for allowing Clause 20 of the first-named Act to pass as it did in its present form. It begins as follows: "Certificates of Cause of Death.—With respect to certificates of the cause of death the following provisions shall have effect." Then follows Section 1, which deals with the furnishing of printed forms of medical certificates to registered medical practitioners, and needs no alteration. Sections 2 and 3 require amendment; hence I give them *verbatim*: "2. In case of the death of any person who has been attended during his last illness by a registered medical practitioner that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death, and such person shall, upon giving information concerning the death or giving notice of the death, deliver that certificate to the registrar, and the cause of death as stated in that certificate shall be entered in the register, together with the name of the certifying medical practitioner. 3. Where an inquest is held on the body of any deceased person a medical certificate of the cause of death need not be given to the registrar, but the certificate of the finding of the jury furnished by the coroner shall be sufficient."

The clause concludes with a requisition for the delivery of the medical certificate to the registrar under a penalty of 40s. Now, these two sections presumably provide for all those cases in which there is no doubt as to the death being a perfectly natural one in all respects, and also for those cases in which there *must* be an inquest. But no notice is taken of the large intermediate class of deaths in which practitioners may have grave doubts as to whether they ought to certify or to refuse to do so. To adopt the first course might subject them to the pains and penalties of Clause 40, which enforces fine and imprisonment for a false certificate, while to refuse a certificate "without reasonable excuse" entails a penalty of 40s.; and even if in adopting the former course the certifying practitioner were relieved from a charge of giving a false certificate, he might still be subjected to great annoyance should an inquest be held and the coroner or jury blame him for giving a certificate at all. On the other hand, the refusal of one, even for the best reasons, subjects him to abuse from the relatives of the deceased; for the giving or refusing a certificate is no longer a matter of choice, but of duty and even compulsion.

The Coroners Act, 1887, Clause 3, defines the following as cases in which the coroner shall issue his warrant for summoning a jury and holding an inquest: "A violent or an unnatural death ..... a sudden death, of which the cause is unknown, or that such person has died in prison, or in such place or under such circumstances as to require an inquest in pursuance of any Act." It is clear that these must comprise many cases in which the deceased had been attended by a registered medical practitioner, who will most certainly be asked to give a certificate. The above Act assumes that the coroner is informed of all such deaths, but does not specify the informant. It seems to me that the first reform required is to amend Section 2 of Clause 30 of the Births and Deaths Registration Act by adding the words, "Should the death have been in all respects a perfectly natural one" between the words "shall" and "sign." The third section might be left as it is, since it will apply to those cases where an inquest is held as a matter of course, and in which a certificate is not asked for—cases of drowning, hanging, murder, manslaughter, accident &c., of which the coroner is informed by the police or other medical informants.

A fourth section should be added. I suggest the following in the hope that all readers of THE LANCET will carefully

peruse them and suggest such alterations and improvements as may occur to them:—"In the case of the death of any person who has been attended in his last illness by a registered medical practitioner, that practitioner shall, should the death have been an unnatural one, or a sudden death of which the cause is unknown, or from violence as a primary cause within twelve months of the death, or should the death have taken place in such place or under such circumstances as to require an inquest in pursuance of any Act, not sign or give a certificate of the cause of death, but shall at once send information of the death to the coroner of the district, either directly or through the coroner's officer or local constabulary." Or the following as an addendum to Section 2: "But no registered medical practitioner is justified in giving a certificate unless he was personally in attendance upon the deceased during the last illness; nor in any of the cases of death specified in Clause 3 of the Coroners Act, 1887. In any or every such case he shall at once inform the coroner of the district," &c., as above.

I am not without hopes that eventually medical practitioners may be remunerated for these certificates, and also that a medical officer analogous to the *médecin vérificateur* of the Continent may be appointed to verify each death, and in other ways to make our Death Registration more perfect. Meanwhile I feel sure that some such changes as I have suggested would tend to simplify the duties of medical practitioners with regard to certificates of death, relieving them from an amount of anxiety and responsibility which they ought not to be called upon to suffer.

I am, Sirs, yours faithfully,

Liverpool, Nov. 5th, 1892.

FRED. W. LOWNDES.

### "EXPERIMENTS UPON ANIMALS."

To the Editors of THE LANCET.

SIRS,—To question the loftiness of Mr. Berdoo's sentiments would be unkind and rude. It would be worse to cast doubt upon the sincerity of his conviction—a conviction opposed to what is held by nineteen out of twenty among physiological and clinical authorities—that experimentation on living animals is so much wanton cruelty, since it never has done and never can achieve anything for the advancement of knowledge which might not as certainly be achieved by other and unobjectionable means. Inspired by the elevated ideas his writings express, strengthened by fervid convictions and with full mastery of the facts, it seems a pity Mr. Berdoo has not chosen to speak for himself rather than yield himself up as the willing instrument of an anti-vivisection propaganda. Of that propaganda the votaries are in the main intelligent, albeit sentimental, individuals who through long contemplation of imaginary evils and atrocities have allowed themselves to become the victims of a fixed idea. Others are less intelligent and still more impressionable, who are willing to accept at second hand any facts, arguments and conclusions which harmonise with their ultra-humanitarian predispositions. This party during some twenty-five years has been engaged in systematic persistent public vilification of a body of high-minded men, of many of whom at least it may without cant be said that they must be included among the select minority in modern society who have throughout led noble lives, men of whose class Pasteur is perhaps the most striking example, men who by sheer force of intellect and hard work have risen to their eminent position, who in a sordid, money-grubbing age have rejected the wealth which their discoveries might have brought them, have given the fruits of their labours freely to the world and have devoted themselves with perfect single-mindedness of purpose to the one object—the pursuit of truth and promotion of scientific knowledge. When Mr. Berdoo complains that "his party does not receive the justice their cause demands," he strangely ignores such facts as these, and appears curiously oblivious of what has been thrust beneath his eyes within the last few weeks in the public press and notably in *The Times*—namely, the statements of injured individuals (physiologists and surgeons) who have brought forward ample proof that they have been most shamefully and foully libelled in the publications of the Society which Mr. Berdoo defends and supports.

I am, Sirs, yours truly,

Wimpole-street, W., Nov. 5th, 1892.

HENRY SEWILL.

To the Editors of THE LANCET.

SIRS,—There is a fallacy in the argument of Mr. Bowreman Jessett which I trust you will permit me to discuss. He

seems to assume that the use of decalcified plates, or some similar contrivance, is essential to the successful union of divided intestine, and concludes that because Senn and others (best of all, my old pupil, Dr. F. Byron Robinson) have made experiments on animals with these plates that the success of intestinal surgery is due to such experiments. No conclusion could be more fallacious.

Years before the experiments of Senn, Robinson or Jessett were ever heard of I had successfully applied the flap-splitting method to the union of intestine. I have used it in some two or three scores of cases, and have failed only once. Nothing could be simpler or more effectual than this method; nothing, in my opinion, could be clumsier than the plates, bobbins &c., which I have seen recommended by various authorities. Resection of the intestine does not differ in any one of the principles involved, nor very much in details. In whatever part of the intestinal canal it is practised "Pylorotomy" has nothing therefore to single it out as a case where experiments on animals are required more than in other parts of the intestine. But if Mr. Jessett wishes to claim for it such a character I will grant his premise at once, because it is one of the class of operations which I utterly condemn. I have never done it, and I never shall, for the disease is malignant nine hundred and ninety-nine times in a thousand, and inevitably returns. In the odd case where the disease is not malignant the operation of pyloric dilatation (Loreta) has been shown to be sufficient. We now know also that such operations as gastro-enterostomy lead to permanent and continuous faecal regurgitation, so that the whole scheme of such operations is gradually being dropped. This is the fate I predicted for them years ago, and if Mr. Bowreman Jessett claims for them an origin in experiments on animals, I gladly let him have it; they are worthy of such a fallacious origin. I know of no operation in intestinal surgery to which I would myself submit which I had not performed many times and many years before the dates given by Mr. Jessett.

I am, Sirs, yours faithfully,

Nov. 8th, 1892.

LAWSON TAIT.

To the Editors of THE LANCET.

SIRS,—Mr. Jessett and Dr. Clarke have mistaken the point of my letter, and it would almost appear from their remarks that I was siding with the anti-research agitators. My object in writing was that the public should have full opportunity of hearing our side of the question, and this can only be done by a more systematic method of educating the public upon the use and morality of animal experimentation than has existed in the past. I would suggest that the published works of the Society for the Advancement of Medicine by Research should be made more public and popular, that the Society should have in readiness one or more trained lecturers to combat the errors of the anti-vivisectionists, and that the pamphlets of the Victoria-street Society should undergo a critical examination; and this last seems now more than ever necessary. The educated people are almost wholly with us; but as almost everyone now has a vote—and one vote is equal to another in a Parliamentary sense—it is necessary to correct the false views of the ignorant, so that a catch vote adverse to scientific research may not be taken in the House of Commons; for, after all, it is with the Commons that the power for good or evil in this matter rests.

I am, Sirs, yours truly,

Folkestone, Nov. 7th, 1892.

W. J. TYSON, M.D. Durh. &c.

### "CHLORIDE OF ETHYL."

To the Editors of THE LANCET.

SIRS,—I am sure that all dental surgeons will be much obliged to Dr. Radcliffe Crocker for the warning he gives as regards the use of chloride of ethyl. I have used it pretty extensively for several months in extracting teeth, making incisions in the gums &c., but I have not observed any of the untoward symptoms which Dr. Crocker's patient exhibited. I use on an average about one-quarter to one-third of a small tube, and I think it advisable to break the neck of the tube as near its extremity as possible, in order to obtain a fine stream and a perfect and rapid evaporation. To effect the same purpose also the tube should be held a considerable distance from the spot to be frozen, say eight to twelve inches. Dr. Crocker's letter, I am sure, will have the effect of placing all users of this anæsthetic upon their guard.

I am, Sirs, yours faithfully,

Harley-street, Nov. 8th, 1892.

WM. RUSHTON.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Moss-side and Incorporation.*

THE old question of amalgamation between this district and Manchester has once more been revived by a recent application on behalf of the Moss-side Local Board for power to borrow some £50,000 for sewerage purposes, one result of this application being a protest on the part of influential ratepayers against this heavy expenditure, and a request that the local board should reopen negotiations for amalgamation with the city, in which event the whole of this outlay would be saved to the ratepayers. The usual inquiry by a Local Government Board inspector has been duly held, but that board have postponed the giving of their decision pending the result of a poll of the ratepayers, which the local board have been requested forthwith to obtain. Strangely enough the Moss-side authorities, although appealed to by a large number of the most important residents in the township, have flatly refused to submit the question to the judgment of the ratepayers. The township of Moss-side is to all intents and purposes a part of the community known as Manchester. The inhabitants of the township avail themselves freely of all our public institutions—the parks, museums, libraries, markets, abattoirs, school boards, hospitals, cemeteries, public baths &c., all of which are supported out of the city rates, but they object to contribute anything to the cost. The position of Moss-side in refusing to bear its due share of a public expenditure, the advantages of which, nevertheless, its inhabitants do not scruple to enjoy, is one which is wholly selfish and unworthy. Should the refusal of the Moss-side board to reopen the question of amalgamation be confirmed by the ratepayers, then the latter, in order to discharge their obligations in regard to the sewerage of their district, will have to submit to a wholly unnecessary expenditure, probably much exceeding the estimated £50,000. And even supposing the sewerage difficulty to have been surmounted by this heavy outlay, it is well known both in the city and in the township that amalgamation will only be postponed thereby, and that its ultimate accomplishment cannot long be delayed.

*Relief for the Sufferers from Cholera.*

On Saturday last an entertainment was given at the Prince's Theatre in this city in aid of the funds of the Association for the Relief of Sufferers by the Cholera Epidemic in Hamburg. The attendance was very large, and the programme of music which was selected by Mr. Wilz Hess was highly appreciated. As a result of the exertions of the relief committee, it is believed that a sum considerably exceeding £500 will shortly be forwarded to the sufferers.

*Fever Hospital Provision for Mid-Cheshire.*

At the last meeting of the Sale Local Board the medical officer of health reported an outbreak of infectious disease within his district. In several of the cases the patients were isolated at the Monsall Hospital, with the fortunate result of staying the spread of what might have been an extensive epidemic of scarlet fever. The medical officer, however, remarks upon the great distance of Monsall, some eight miles from Sale, as being a serious drawback to the extensive use of the hospital by the inhabitants of his district. The present would appear to be a convenient opportunity for reopening the question as to whether fever hospital accommodation for the whole of the rural districts of this county should not forthwith be provided. The Mid-Cheshire sanitary districts might usefully combine for this purpose and provide two or more small hospitals at suitable parts of the county, which would be available for such an emergency as that which has lately befallen the Sale Local Board.

*The Unemployed in Manchester.*

At a recent meeting of the Manchester Guardians it was reported that a considerable increase in the number of vagrants had recently taken place. Careful inquiry revealed the fact that these vagrants are not all of the "loafer" class who usually frequent our tramp wards, but that at the present time there are many artisans out of work. The men appear to be tramping from place to place in search of work, which just now seems to be scarce. The annually recurring and difficult problem of how best to deal with the unemployed who in the winter months present themselves for relief in such large numbers at the workhouse doors is this year still further

complicated by the circumstance that some 50,000 of the cotton workers of the district have "gone out on strike" rather than submit to a temporary 5 per cent. reduction in their wages, which reduction the Masters' Association declares to be inevitable. The outlook for the coming winter is indeed a gloomy one.

*Stretford and Artisans' Dwellings.*

The local board of Stretford have recently determined to put in operation the Housing of the Working Classes Act for the demolition of a block of insanitary property known as Diamond-court, which has long been regarded as an eyesore in the district. Something less than 200 persons will be displaced by this scheme, which involves the clearing of the land and the rehousing of about half the people on an adjoining site which is to be purchased from Sir Humphry de Trafford. The land in this neighbourhood is steadily becoming more valuable by reason of its proximity to the docks of the Manchester Ship Canal, and this board are of opinion that on this account the carrying out of their first scheme under the Housing of the Working Classes Act will add very little to the rates of the district.

*Clinical Society of Manchester.*

The annual meeting of the above Society was held on Tuesday, Nov. 1st, when the following officers were elected:—President: Dr. T. C. Raitton. Vice-presidents: Dr. James Holmes and Mr. C. F. H. Kitchen. Treasurer: Dr. C. H. Braddon. Librarian: Dr. J. F. Le Page. Committee: Mr. W. Bain, Dr. H. W. Boddy, Dr. E. Stanmore Bishop, Dr. S. Buckley, Dr. J. Brassej Brierley, Dr. K. M. Chisholm, Dr. J. C. Eames, Dr. J. Earle, Dr. A. Hirst, Mr. W. E. Husband, Dr. W. Milligan, Dr. C. G. L. Skinner, Dr. A. Wahltuch, Mr. R. W. Walsh, and Dr. J. B. Wilkinson. Auditors: Mr. E. Roberts and Mr. J. Paulin. Hon. Secs.: Dr. A. Hill Griffith and Dr. Herbert Lund.

Manchester, Nov. 8th.

## MIDLAND COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

*Hospital Sunday, Birmingham.*

Sunday, Oct. 31st, was the appointed day for the collections. The amount contributed was £4715 1s., which this year goes to the General Hospital.

*The Tendencies of the Age.*

These tendencies may be gathered from the wording of a debate which took place at the Birmingham and Edgbaston debating society on the 2nd inst. It was announced as follows:—"That as the hospitals of the city, which exist for the benefit of the whole of the community, and especially for the benefit of the medical profession, are now so largely supported by the artisan classes they should be considered cooperative institutions rather than charities." This proposition was ably argued and strongly contested, with the result that it was lost by a large majority.

*Corporal Punishment in Birmingham Board Schools.*

This subject has lately given rise to considerable agitation among the teachers in the city schools, owing to one of the head masters having been fined for an assault. The certificated teachers of the Board schools complain that the regulations on this matter are a constant source of worry, greater than all the other scholastic difficulties put together. They have decided to memorialise the board, and to endeavour to get the subject discussed apart from prejudice and feeling.

*Drug Stores.*

There are, it was said at a meeting of the Midland Counties Chemists' Association, oil and colour stores where drugs are sold by unqualified men in direct contravention of the Pharmacy Act, prescriptions being dispensed and poisons sold in such a manner as to make the Act a delusion and the sale a snare to unsuspecting persons. No doubt this can be remedied by some vigilance on the part of the Pharmaceutical Society. Counter-prescribing also is an evil which affords abundant scope for being rectified; a few examples of punishment would go far to check the harm often done in this manner and would be a protection to the public.

*Hospital Dinner.*

At the General Hospital, Birmingham, on the 2nd inst., a dinner was given by his colleagues on the committee to Sir

John Jaffray, Bart., in recognition of the honour conferred upon him, and of his long association with the hospital. The proceedings were marked by enthusiasm, by interesting retrospects and hopeful promises for the future.

Nov. 9th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *The Deaf and Dumb in the North.*

At a meeting of the Committee of the Deaf and Dumb Institution in Newcastle for the Northern Counties it was decided to take steps to extend the building. This resolution was proposed by the chairman, Dr. Philipson, and was carried unanimously. The present building was erected upwards of twenty-five years ago, when the inmates numbered only sixty, and was constructed to accommodate ninety. The present number of pupils under instruction is 126, and upwards of twenty other cases are eligible for admission. It is estimated that the last census, not yet published, will show that in the four northern counties for which the institution was established the number of deaf and dumb children of school age is from 190 to 200. When the Education Bill (Deaf and Dumb) now pending becomes law and attendance becomes compulsory, accommodation will have to be provided for this number.

### *St. John Ambulance Association, South Shields Centre.*

The annual report of the St. John Ambulance Association, South Shields Centre, shows that the work of the Association is progressing. The number of candidates who received first-aid certificates and medallions was 274. Seventy-one railway employes have passed through the classes during the year.

### *The Thirsk Railway Accident.*

It is reported from Thirsk to-day that the driver of the Scottish express, Ewart, who is in a very critical state, has passed a bad night. Mr. Buchanan is said to be doing well. Head, the fireman, is also said to be doing well. Mr. Fred Page, surgeon to the Newcastle Infirmary, has been requested by the company to visit some of the injured.

### *Small-pox in Yorkshire.*

An outbreak of small-pox is reported as having occurred at Otley, not far from Leeds. Twenty persons are known to be affected. Prompt steps are being taken to stamp out the epidemic, and among other measures a temporary hospital is being erected and vaccination and revaccination are being adopted upon a large scale. It is hoped that the affection may be prevented from spreading into the large towns.

### *Typhoid Fever in Durham County.*

In the Chester-le-Street sanitary authority and other districts in the county of Durham there has been observed a growing increase of typhoid fever. Dr. Duncan of Chester-le-Street says that, as well as forty-eight notifications of scarlet fever during the month, twelve cases of typhoid fever have been notified. In one house there were three cases of typhoid fever; in the same house there was an outbreak of that disease last year.

### *Death from a Kick at Football.*

On Saturday last a boy named Harold M. Stevenson, eleven years of age, a pupil at the Society of Friends' school at Wigton, near Carlisle, died from the effects of a kick whilst playing football in the school ground on the previous Saturday. During the match there was a scuffle and the boy sustained injuries on the thigh, and his death resulted after much suffering.

### *The Dangers of Gas-heating for Baths.*

I have frequently recorded in these notes fatal accidents from gas escaping in bath-rooms. If the gas is imperfectly lighted or the fumes of the combustion are not allowed to escape there is certain to be peril in the bath-room. Last week two boys were found insensible from this cause in a bath-room at South Shields, and it was shown that had it not been for the promptness with which two police-constables acted in performing artificial respiration the boys would have died.

### *The Tramp Question.*

The master of the Knaresborough Union, Mr. G. Paul, has just read a paper on Vagrancy at a conference of the Poor-law unions of Yorkshire, in which he holds that three-fourths

of the tramps are irreclaimable, and he contends that it is a disgrace to society that hundreds of poor children should be left in the hands of merciless and remorseless men and women, to be dragged over miles of country, through suffering, sin and shame. Of the remaining fourth of the vagrants, Mr. Paul asserted that a large proportion were Army Reserve men or men who had been in the army, and unless something were done he was afraid that the ranks of the professed tramp would be recruited from this section. Of the remainder, he found that the tramp ward was a sanctuary to those fleeing from justice. To remedy this condition of things he suggested that something more ought to be attempted in the way of providing employment for discharged soldiers and sailors, and the honest casual might be provided with a "livret" stating the course of his journey, and thus passing him from one union to another without difficulty.

### *Poison in the Porridge.*

At Rotherham last week Mrs. Woods, Albert Woods (her son), and a lodger named Middleton, after partaking of oatmeal porridge, were seized with symptoms of poisoning. The two men died the next morning. Middleton was a rat-catcher, and the supposition is that some poison used by him had become accidentally mixed with the oatmeal used for the supper porridge.

### *Great Run of Salmon in the Solway.*

There was a great run of salmon in the Solway rivers last week. For some weeks previously the low condition of the rivers has caused salmon to gather at the mouths of the rivers on their way up to the spawning beds, but one day placed the rivers in excessive floods, and when they commenced to fall immense numbers of salmon ran up. During the course of one afternoon many hundreds of fish were seen going over the falls at Annan Bridge. Many of the salmon were judged to be over 36 lb. in weight. A whale, measuring 43 ft. in length, was last week towed into Aberdeen by the Grimsby smack, *Catherine*. The monster was caught off our Northumberland coast near the Farne Islands. The seal a few years ago was common enough about the Farnes and Holy Island, but I believe it has not been often seen of late. I suppose the steamer traffic on the coast has disturbed it from its habitat.

Newcastle-on-Tyne, Nov. 9th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The Edinburgh Medical Societies.*

THE Medico-Chirurgical Society held the first meeting of its seventy-second session on Wednesday of last week. Dr. Joseph Bell continues in the presidential chair for the new session. Dr. Troup, the treasurer, having resigned, Dr. Mackenzie Johnstone was appointed to the post, and Mr. F. M. Caird, one of the secretaries, was succeeded by Mr. Hodsdon, and Dr. W. Russell was reappointed. Dr. W. Craig was reappointed editor of the Transactions. The meeting was held in the Royal College of Physicians, which had been kindly lent, as the Society has been unable to find a suitable place of meeting and it has no hall of its own. The first item of public business was a paper by Dr. William Russell on Some Practical Results of the Investigation of Cholera in Germany, with a demonstration of the comma bacillus and its appearances in plate and tube cultures. The paper referred to his experience in Berlin and Hamburg. It led to considerable and varied discussion, and on the motion of Dr. James Ritchie, seconded by Dr. Allan Jamieson, it was unanimously agreed that it be remitted to the Council to memorialise the Lord Provost and the Public Health Committee, with the view of having bacteriological laboratories established in connexion with each cholera hospital, supervised by a properly instructed medical man. The second item on the billet was a paper by Mr. A. G. Miller on Arthroctomy of the Knee-joint, giving the results of thirty-five cases. Owing to the late hour Mr. Miller, unfortunately, could only give an abstract of his paper, and there was no discussion on it, which is to be regretted, as the subject is such an important one. From the abstract, however, it appeared that Mr. Miller had obtained excellent results in thirty out of the thirty-five cases. The paper will be published in full.—At the first meeting of the Pathological Club Dr. Noël Paton was appointed secretary, in succession to Dr. A. Bruce.

*Typhus Fever in Leith.*

During the past week there have been 8 new cases of typhus fever in Leith, against 7 in the preceding week. The epidemic of measles and of scarlet fever continues.

*Health of Edinburgh.*

The mortality last week was 127, making the death-rate 25 per 1000. Diseases of the chest caused 46 deaths and zymotic diseases 37, of which 34 were due to measles. The intimations for the week comprised: typhoid fever, 4; diphtheria, 2; scarlet fever, 59; and measles, 368.

*Glasgow: Small-pox and Scarlet Fever.*

The most striking features of the last public health report are the unusual prevalence of small-pox and scarlet fever. A fortnight ago the presence of the former disease in the city in a mild form was recognised and medical practitioners were warned of its existence. As was expected, the disease has spread, and in the beginning of this week no fewer than twenty-four cases of small-pox were recognised. This is by far the largest number certified since the spring of 1884. All the cases are more or less modified by vaccination in infancy. The epidemic of scarlet fever shows no sign of abating; beginning in one of the southern districts in August last, it has since steadily spread. Four weeks ago 970 cases were reported, three weeks ago 1029 cases, two weeks ago 1103, a week ago 1194, and at the beginning of the present week 1235 cases. Of these, 875 are in hospital. In presence of this enormous increase of fever patients the sanitary authorities find themselves in a difficulty. The hospital accommodation is now strained to its utmost, and already some of the space reserved as a rule for small-pox has been occupied with scarlet fever cases. As there is every likelihood of small-pox as well as scarlet fever spreading still further, the sanitary authorities have approached the town council for "full powers to take such steps as in their judgment they may think necessary to meet the circumstances of the case." To the credit of the council, the gravity of the situation was recognised and the requisite powers were granted.

*Conversazione to Nurses &c. at Glasgow.*

The close of Sir John Muir's reign as Lord Provost of Glasgow has been marked by a kindly and graceful act of hospitality—a conversazione in the municipal buildings, to which were invited the directors, medical and surgical staff and the nurses of the various infirmaries and other similar institutions in and around Glasgow. A company of about 800 responded to the invitation. Short addresses by Sir John Muir, Professor Macewen and others, some excellent music and dancing, passed the time pleasantly till midnight. The nurses appeared in their ward dresses, a feature which lent unusual colour and interest to the assembly.

*Royal Infirmary, Glasgow.*

Professor Macewen's former place on the staff of the Royal Infirmary is now occupied by Dr. D. Newman, whose appointment has just been announced. Dr. Samson Gemmill's removal from the Royal to the Western Infirmary leaves a vacancy on the physicians' side of the staff which has not yet been filled up, though it is expected that Dr. Geo. J. Middleton will gain the coveted step.

Nov. 10th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Royal College of Surgeons.*

AN election for a member of Council in the room of Mr. Barton, resigned, will be held on Monday, the 14th inst. In addition to the name of Professor Heuston, already mentioned, may now be added that of Dr. Cranny.

*Royal Academy of Medicine.*

The first meeting of the Academy for the present session took place on Friday evening, the 4th inst. The first paper in the Section of Pathology was a Case of Traumatic Malignancy, which was read by Mr. Graves, and which occurred in the practice of Dr. Wheeler. Three weeks after an injury received there was malignant sarcoma of bone

formed which necessitated amputation above the knee. Dr. Bennett, who presided, mentioned a case where malignant sarcoma occurred within three weeks without any injury having been received. Recurrence, he added, generally takes place in some internal organ.

*Richmond Hospital Dinner.*

The annual dinner of the medical staff was held at the Shelbourne Hotel on Saturday last. The toasts included the "Universities and Colleges of Ireland," "The Staff" and the health of the chairman, Mr. William Thomson.

*Dublin Hospital Sunday.*

The annual collections in aid of the Dublin hospitals will be held on Sunday next, the 13th inst. Last year the total receipts amounted to £3982 19s. 5d., being a decrease of £205 3s. 6d. as compared with the previous year; while the total amount collected since the foundation of the fund is £73,469 16s. The hospitals' football match will take place on Saturday next, when teams from the county Dublin and the united hospitals will have a friendly contest.

*Rotunda Lying-in Hospital.*

Sir George H. Porter, Bart., M.D., surgeon-in-ordinary to Her Majesty and senior surgeon to the Meath Hospital, has been appointed consulting surgeon to the Rotunda Hospital, in the room of the late Surgeon Colles.

*The Ulster Medical Society.*

The first annual meeting of the Ulster Medical Society for the present session was held on Wednesday, Nov. 2nd, when Dr. O'Neill, President, resigned the chair into the hands of the incoming President, Dr. Whitaker, medical officer of health for the city of Belfast, who delivered a very interesting address on sanitation and public health, for which he was accorded the hearty thanks of the Society on the motion of Mr. M'Connell, seconded by Professor Whitla. The Society then considered and passed the annual report and also a code of rules (with several alterations) in reference to medical ethics.

*The Winter Session at the Medical School, Belfast.*

The winter session of the Medical School began on Nov. 1st, when Dr. Nelson gave the introductory address at the Royal Hospital, before a very large audience of the students and the medical staff. He strongly advised the students to study at the bedside, and recommended accuracy in diagnosis as of the utmost moment. He showed, by a number of clinical cases, how, in ophthalmic practice, the symptoms might be very much alike to a careless observer in many different conditions, and he emphasised the fact that treatment could only be scientific and accurate when based on a sound diagnosis. The only change at the hospitals is the resignation of Dr. Burden, pathologist to the Royal Hospital. All his colleagues regret sincerely that, owing to serious illness, he has been obliged to retire. No successor has yet been appointed. At Queen's College, Belfast, Dr. Dill, Professor of Midwifery, has, through ill health, been unable for the present to meet the class. Dr. John W. Byers has been appointed as locum tenens and began lecturing on Tuesday.

*Belfast Branch of the Royal Medical Benevolent Fund Society of Ireland.*

At the quarterly meeting held last week a letter was read from the hon. secretary, Dr. H. Burden, tendering his resignation owing to ill health. A resolution was passed accepting Dr. Burden's resignation and placing on record the sense that the members felt of the valuable services rendered by him to the Society during the past eight years, and sincerely regretting the serious illness with which he is afflicted, and tendering their sympathy to his family and himself. Dr. John McCaw was appointed as secretary until the annual meeting.

Among the passengers of the ill-fated *Roumania* was Miss Mary E. M'George, an Irish lady, belonging to the Zenana Mission.

Mr. F. Odevaine, F.R.C.S.I., has been elected ophthalmic surgeon to St. Vincent's Hospital, Dublin.

Cork Hospital Saturday collections have realised £349.

The death is reported of Francis Dancy, Hamilton, F.R.C.S., at Navan, on the 3rd inst. Mr. Hamilton was late surgeon to the County Meath Infirmary.

Nov. 9th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Hydrochloro-sulphate of Quinine.*

IN utilising the anti-malarial properties of quinine in fever districts economical considerations militate strongly in favour of the hypodermic method of administration. The soluble salts of quinine which are at our disposal for this purpose are: the acid sulphate (solubility 1 in 12 of water), the lactate (1 in 10), the acid hydrobromate and the hydrochlorate (each 1 in 6). To these salts must now be added yet another, the hydrochloro-sulphate, discovered by M. Grimaux (*Société de Biologie*, Oct. 29th). This double salt is said to be soluble in its own weight of water at the ordinary temperature, a great advantage for injecting purposes. In the crystals, which contain three molecules of water, the proportion of the alkaloid is 74.21 per cent. The density of the crystals allows of its administration in effectual doses in much smaller wafers than is the case with the light feathery sulphate. The therapeutic properties of this new addition to our anti-periodic drugs have been studied by M. Laborde, and he pronounces them to be fully equal to those of the ordinary sulphate, its effects being, however, more rapid.

*Cholera and Inoculation.*

Some remarkable facts relating to the prophylaxis and even cure of cholera by inoculation have lately been elucidated by Dr. Ketscher of St. Petersburg, whose researches, conducted in Paris in Professor Strauss' laboratory, formed the subject of a communication made to the *Société de Biologie* on the 29th ult. by M. Gamaleia. For the experiments leading up to the discovery the most intensely virulent cultures of cholera germs hailing from Massouah were employed, the subcutaneous intra-peritoneal and intra-venous methods being all had recourse to. In order to test the protective powers of the milk of inoculated goats it was injected into the peritoneal cavity of guinea-pigs. The injection of 5 cc. of the milk conferred complete immunity on guinea-pigs against a fatal dose of cholera culture of  $\frac{1}{2}$  cc. injected into the peritoneal cavity, while animals not injected invariably succumbed in from six to ten hours. In order to prove that the milk conferred resisting powers on the entire system of the guinea-pig, and did not merely destroy the virulent germs, it was injected into the peritoneal cavity while the dose of cholera poison was introduced into the muscles of the hind leg. The result was identical—the inoculated animals survived while the unprotected ones died. The precaution was taken of testing the presence of any protective properties in the milk of goats which had not been inoculated, and the absence of such properties was conclusively demonstrated.

*Professor Verneuil's Farewell Lecture.*

No Paris surgeon is probably better known abroad than Professor Verneuil. Many hundreds of our compatriots must have followed him through his wards at the Pitié and Hôtel Dieu Hospitals. His geniality has endeared him to generations of students, while his facility of expression and clearness of language have rendered his clinical lectures models of scientific eloquence. The rapid approach of the age limit prescribed by the regulations of the Paris faculty would in the ordinary course of things soon have compelled the retirement of this distinguished surgeon from the chair of clinical surgery, which he has so well filled for many years. He has anticipated that event by tendering his resignation, and on Saturday last he made his last bow as a lecturer to a crowded audience assembled under the presidency of the Dean, Professor Brouardel, in the large amphitheatre of the Faculty. Many of the retiring professor's colleagues were present, and the appearance of the veteran *confrancier* at 8.30 p.m. was the signal for loud and prolonged cheering, which was renewed again and again at the end of the lecture.

Nov. 9th.

LITERARY INTELLIGENCE.—*La Semaine Médicale*, which has for some little time been publishing a Spanish edition, announces that this venture has been so successful that arrangements are being made to publish an English edition. The first number will appear next month.—A new Belgian medical journal, *La Polémique de Namur*, has just appeared. It will be published monthly.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the Royal College of Surgeons, held on the 10th inst., Mr. Thomas Bryant, President, in the chair the minutes of the quarterly meeting of the Council of Oct. 13th were read and confirmed.

The minutes of the committee for general purposes were read and confirmed, and it was agreed that the following be the regulations of the common room for Fellows and Members:—1. The common room is open only to Fellows and Members of the College. 2. The common room is open on each week day from 11 A.M. to 5 P.M., except Saturday, when it is open from 11 A.M. to 1 P.M. It is closed during September, and at such other times as the Council may direct. 3. No formal meeting of any description may be held in the common room. 4. Fellows and Members writing letters at the College may not use the College as their address. N.B.—Fellows and Members are reminded that smoking is not permitted in any part of the College buildings. It was also decided that, as recommended by the committee, writing materials and such journals and newspapers as the committee may from time to time determine be provided for the common room. This room will be opened on Dec. 1st.

It was agreed to carry out alterations in the drainage of the College premises at an estimated cost of over £150. It was agreed, on the recommendation of the Conjoint Board, to recognise instruction in chemistry, physics, practical chemistry and elementary biology at the following institutions as fulfilling the requirements of the regulations for admission to Parts 1 and 3 of the First Examination—viz., University College, Bristol; the Public School of Science, Cheltenham; the School of Science and Art, Chester; the Merchant Venturers' School, Bristol.

The President reported the proceedings at the meeting of Fellows and Members on the 3rd inst., and stated that, in addition to sixteen members of the Council, there were present at the meeting twenty-seven Fellows and forty-three Members.

He also read the following motion, brought forward at the meeting and not carried, ten voting for and sixteen against the same—viz.: "That this meeting of the College of Surgeons of England is of opinion that the report now presented is ineffective and incomplete"; and the following resolutions carried at the meeting—viz.:

1. "That this meeting is of opinion that the ancient attitude of hostility on the part of the Council to the true interests of the body corporate of the College ought to terminate, and that the repeated resolutions passed at former meetings of this College should be carried into effect." Carried by twenty-five to ten. With regard to this resolution it was agreed that the mover and seconder be informed that the resolution has been laid before the Council.

2. "That this meeting of Fellows and Members be desired to thank the Council of the College for acceding to their wishes in the matters (a) of separate meetings of Fellows and Members and (b) of the provision of a common room in the College." Carried, with one dissentient. The mover and seconder to be informed that their resolution has been received by the Council with thanks.

3. "That this meeting of Fellows and Members wishes again to impress upon the Council that it is absolutely essential for the welfare of the College that the Fellows and Members should be consulted before any change is made in the constitution and external relations of the College, and before the College be committed to any extraordinary expenditure on buildings or otherwise." Carried by twenty-two to two. The mover and seconder to be informed that the resolution has been laid before the Council, and that they be referred to the following extract of minutes of the Council dated Nov. 17th, 1885:—"With the larger questions which more rarely arise, such as those which concern the constitution of the College, the case would be different. On these questions the Council will always be glad to have an opportunity, so far as practicable, of consulting the Fellows and Members."

The Council elected a committee on the arrangements for the jubilee of the Fellowship. The following were appointed: Messrs. Hulke, Willett and Harrison, with the President and Vice-presidents, and they were authorised to add to their

number Fellows not on the Council, to consult about the arrangements for the dinner.

Permission was granted to Mr. James Galloway to deliver the Morton lecture in the theatre of the laboratories on the Embankment. This lecture to be given on Feb. 2nd, 1893, at 4 P.M.

The President stated that the vacancy on the Court of Examiners which would be occasioned by the expiration of Mr. Heath's period of office on Dec. 8th next would be filled up at the ordinary meeting of the Council on that date.

## Medical News.

**UNIVERSITY OF EDINBURGH.**—The following candidates have received the degrees of Bachelor of Medicine and Master in Surgery:—

William Corsar Anderson, Scotland; Arthur Reginald Bankart, Wales; Frederick Morrison Black, Scotland; Nathaniel Troughton Bond, England; W. J. Walker Winfield Borthwick, Scotland; John W. Parker, Scotland; Albert Cameron, Scotland; Archibald Nathaniel Shirley Carmichael, Scotland; Jas. Ojaye, Coker, Africa; Jas. Cowie, Scotland; Victor Mackay Daly, India; Robert Huoh Drannan, Ireland; Alexander M'Beth Elliot, Scotland; John Robert Foster, England; David Fraser, Wales; Murray Gillespie, Scotland; Thomas Arthur Granger, Scotland; Percy Frere Grant, Scotland; Frederick Thresher Griffin, England; Josiah Field Hall, England; Arthur Ainslie Hudson, England; John Edmund Knox, England; Henry Latham, England; Andrew Thomson Law, Scotland; William Lawton, England; Arthur William Bligh Livesay, England; George Francis Longbotham, England; David William Knuyett Lyall, India; Alexander Minto M'Donald, Scotland; James McFarlane, Scotland; Angus Vallance M'Gregor, Scotland; Murdo Mackay (M.A.), Scotland; William Crawford Macknight, Australia; William M'Lean, Scotland; Thomas Muirhead Martin, Scotland; Charles Edmund Maude (B.A.), New Zealand; Rodon Tregarthen Michell, India; John Oswald Morrison, Scotland; Donald Geo. Macleod Munro, Scotland; Andrew Newall (B.A.), Scotland; Alan Anderson O'Hara, Australia; John Owen, Wales; Malcolm Parkinson, England; Horace James Pechell, England; John Donald Pollock, Scotland; Walter Midgley Robertshaw, England; Arthur Clement Staenberg, India; Cecil Edward Stephens, England; John Boll Thomson, New Zealand; Frederick Richd. Van Langenberg, Ceylon; Alban Ward, England; Alfred John Wheatley, England; Charles Webster Williams, Wales; Griffith Jones Williams, Wales; James Gordon Williamson, on India.

The following candidates were successful at the B.Sc. (Public Health) Examination:—

Robert Martin Beattie (M.B.), New Zealand; John David Williams (M.B.), Wales.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.**—The following candidates have passed the Final Examination:—

W. H. Anderson, M. Brick, A. Callaghan, C. R. Chichester, J. Crumley, H. C. Falkner, G. A. Fleming, A. A. Hargrave, R. G. Hayden, M. C. Jordan, F. A. Madden, P. F. Monaghan, A. C. McCutcheon, W. H. Parr, C. M. Richards, Jas. Robinson, F. Warren, S. W. Wilson, T. F. Wyse.

*Passed Medicine Group.*—A. Banks, J. W. Burne, J. J. Callanan, T. C. Cummins, W. H. Langley, F. W. Perry, J. J. Rogers, A. H. White.

*Passed Surgery Group.*—A. Banks, T. C. Cummins, J. V. Griffin, W. H. Langley, E. C. Murphy, J. O'Brien, F. W. Perry, R. R. Smith, J. A. Smullan, W. A. Wills.

*Passed Midwifery Group.*—J. W. Burne, F. C. Bushman, C. E. Cowan, J. V. Griffin, C. A. Hagman, E. C. Murphy, H. J. McCormick, J. T. O'Brien, F. J. Rogers, and R. R. Smith.

The following candidates have passed the Preliminary Examination:—

W. E. Beamish, C. J. Buchanan, J. Campbell, B. J. Connellan, R. L. Davies, M. J. Dillon, D. J. Farrell, S. L. Glynn, D. P. Holland, P. J. Horkan, M. J. Hynes, J. W. Langstaff, J. J. O'Brien, E. E. Roberts, T. J. White, and R. N. Woodley.

*Physics only.*—C. W. Caldwell, F. C. Fowler, A. McMunn, P. M. Sidpworth, and F. Stoker.

**MATER MISERICORDIÆ HOSPITAL, DUBLIN.**—The following appointments have been made:—House Physician: J. O'Donnell. House Surgeon: J. Redington.

**THE GENERAL PRACTITIONERS' ALLIANCE.**—A meeting of the Council of this Society was held at the offices, 11, Adam-street, Strand, on Wednesday, Nov. 2nd. Dr. Hugh Woods reported that the committee appointed to consider the matter were of the unanimous opinion that it was desirable, before undertaking any financial business for the members, such as the collection of debts &c., to register the Alliance as a limited liability company. It was resolved to convene a special meeting of the Council to consider the report.

**SMALL-POX** is still maintaining its foothold in the West Riding of Yorkshire, although it seems to have left the districts in which it first appeared some eighteen months ago and to have spread to fresh fields. It has now, we regret to learn, broken out at Otley in Wharfedale.

**A PROFESSOR CHARGED WITH FORGING DIPLOMAS.**—At Bow-street, on Tuesday, Ludwig Ganting, professor of languages and music, was brought before Mr. Vaughan for extradition, charged on remand with having stolen the seals and forged the diplomas of the University of Berne. Mr. Crawshaw defended. Detective-sergeant Wegner stated that since the last remand he had searched the prisoner's effects and found three seals—one of the Berne University, one of the medical faculty and one of the philosophical faculty. He also found a press used for affixing seals. Among other things he found a number of diplomas. One of them bore seals which appeared to have been impressed by the moulds in the prisoner's possession. It was signed by Studer, rector, and by a professor. The witness added that he found a number of letters addressed to the prisoner from all parts of the country. It appeared from these that he had been in communication with medical gentlemen, and had offered to let them have diplomas for a consideration. Some of the letters were in German, but most of them were in English. Mr. Vaughan, who examined one of the diplomas and said it appeared to be genuine, remanded the prisoner.

**FOOTBALL CASUALTIES.**—In a match at Fir-grove, on the 29th ult., between the teams representing Farnham and New Town, Aldershot, one of the visiting forwards collided with an opposing half-back and seriously injured his arm.—On the same day, during a match between Dereham and Fakenham teams, the Dereham ground keeper fractured one of his legs just below the knee.—On Saturday, in a game with the Handsworth team, a player fractured his clavicle and was admitted to the district hospital, and a youth in a school match in Dartmouth Park collided with another player, fracturing his arm, and was also admitted to the district hospital.—On the same day, during a game between the Rudge United and Hinckley Trinity teams at Coventry, a forward of the home team fractured his clavicle.—On the 1st inst., during a match between the Farsley Tradesmen and the team of the Duke of Wellington's Regiment, now stationed at Bradford Moor, a player fractured one of his ribs.—On Monday, in a county match at Camborne, a Redruth player fractured his clavicle.—On Tuesday, during the progress of a match at Gosport between the Royal Marine Light Infantry and the Oxfordshire Light Infantry, a player "broke his ankle."

**THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED: SOUTH-WEST LONDON DIVISION.**—The first meeting of the members of the South-West London Division was held (by permission of Dr. Keen) at 211, King's-road, Chelsea, on Nov. 9th. Dr. Matthew Baines was elected to the chair. The chairman then called upon Dr. George Mead to explain the constitution and motives of the London and Counties Medical Protection Society, Limited. Dr. George Mead, having briefly sketched the history of the Society, its aims and administration, replied to various questions asked by the members present. It was then proposed by Dr. Keen, and seconded by Dr. McCaskie, that "The South-west London Division of the London and Counties Medical Protection Society, Limited, be hereby constituted." This was carried unanimously. The following officers of the division were then duly elected:—President: Matthew Baines, M.D. Lond., M.R.C.S., South Kensington. Vice-Presidents: Norman McCaskie, M.D., C.M., South Kensington; William Keen, M.D., M.R.C.S., Chelsea; C. H. Gage-Brown, M.D., M.R.C.S., Chelsea; E. Seton Pattison, L.R.C.P., M.R.C.S., Fulham. Members of Council: George Coates, M.A., M.D., M.R.C.S., and H. D. Waugh, M.D., B.Sc., M.R.C.S., South Kensington; J. Foster Palmer, L.R.C.P., M.R.C.S., Chelsea; H. Des Voux, M.D., M.R.C.S., Westminster; L. Vernon Jones, M.B., B.Ch., B.A.O., St. James's. Hon. Sec.: Alex. G. R. Foulerton, L.R.C.P., M.R.C.S., D.P.H. Camb., 122, Brompton-road, S.W. It was decided that the Council should have power to add to their number two vice-presidents and six additional members of Council. Votes of thanks to Drs. Matthew Baines, Mead and Keen having been passed unanimously and duly acknowledged, the meeting then terminated.

**ST. VINCENT'S HOSPITAL, DUBLIN.**—The following appointments have been made:—Resident Physician: James P. Marnell. Resident Surgeon: James F. Barrett.

**JERVIS-STREET HOSPITAL, DUBLIN.**—The following prizes have been awarded for the past session:—Senior: Gold Medal, G. Hamilton; Silver Medal, A. McCann. Intermediate: Silver Medal, H. Moffat. Junior: Silver Medal, E. Calligan.

**THE GRESHAM UNIVERSITY.**—The Rev. Dr. Wace and Professor Gault, representing King's College, and Professor Hudson Beere, as a representative of Civil Engineering, gave evidence on Wednesday last before the Gresham University Commission.

**UNIVERSITY OF CAMBRIDGE.**—The dates for the examinations for medical and surgical degrees for the present Michaelmas term are as follows:—First examination—Part I.: Dec. 6th, 7th, 8th and 9th; Part II.: Dec. 7th and 12th. Second examination—Part I.: Dec. 12th, 13th and 14th; Part II.: Dec. 6th, 7th, 8th, 9th, 10th and 12th.

At the monthly meeting of the Royal Institution of Great Britain on Monday last the special thanks of the members were returned to the Goldsmiths' Company for their generous grant of £1000 "for the continuation and development of the valuable original research which the Society is engaged in carrying on; and especially for the prosecution of investigations on the properties of matter at temperatures approaching that of the zero of absolute temperature."

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADAMS, E. W., M.R.C.S., L.R.C.P., has been appointed House Accoucheur to King's College Hospital.

ADAMS, W. F., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

ARNISON, W. C., M.D. Durh., M.R.C.S., has been reappointed Honorary Surgeon to the Newcastle-on-Tyne Royal Infirmary.

BLACK, W. G., F.R.C.S. Edin., has been appointed Honorary Assistant Surgeon to the Royal Infirmary, Newcastle-on-Tyne, vice Dodd, resigned.

BOND, C. HUBERT, M.B., C.M. Edin., M.P.C., has been appointed Resident Clinical Assistant to the West Riding Asylum, Wakefield.

BOTHWELL, G. GRANVILLE, M.B., C.M. Aberd., has been appointed Assistant House Surgeon to the Royal Surrey County Hospital, Guildford, vice Walker, resigned.

CLARKE, J. JACKSON, M.B. Lond., F.R.C.S., has been appointed Assistant Surgeon to the North-west London Hospital, Kentish Town-road.

DENT, LOUIS W., L.R.C.P. Lond., M.R.C.S., has been appointed Deputy Medical Officer, Ewell.

DUFF, W. W., M.D., B.Ch. Irel., has been appointed Medical Officer for Aghalee, Lurgan Union, vice Scott, resigned.

FREELAND, REGINALD STILWELL, M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Resident Medical Officer to the Pay Wards, Guy's Hospital.

FOOT, E. G., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Fetworth Union, vice Rutherford, resigned.

HAYCOCK, H. E., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Thirteenth Sanitary District of the Basford Union.

HAYES, W. A., M.R.C.S., L.R.C.P. Lond., has been appointed Poor-law Medical Officer for the No. 2 Division of the Calne Union.

HIGGINS, O. E., M.A., M.B., M.R.C.S., L.R.C.P., has been appointed Medical Officer to the Hastings and St. Leonards Provident Dispensary.

JACKSON, A. C., M.R.C.S., L.R.C.P. Edin., L.M. Lond., I.M. Edin., has been appointed Medical Officer to the Princess Christian Cottage Hospital at Sierra Leone.

JAER, H. I., L.R.C.S., L.R.C.P. has been appointed Ophthalmic Clinical Assistant to King's College Hospital.

LEGGATT, G. S., M.R.C.S., has been appointed Medical Officer for the Out-door Poor and the Workhouse of the Hoo Union.

MACKENZIE, JOHN CUMMING, M.B. &c., Deputy Medical Superintendent of the Northumberland County Asylum, Morpeth, has been appointed Medical Superintendent of the Northern Counties Asylum, Inverness, vice Aitken, deceased.

MARTIN, T. BERRELEY, L.R.C.P., L.R.C.S., L.S.A., has been appointed Medical Officer for the Bishop Wearmouth West District of the Sunderland Union, vice Burns, resigned.

MONAGHAN, T. JOS., L.R.C.P., L.R.C.S. Edin., D.P.H., has been appointed Medical Officer to the Accrington Town Council.

MORTON, EDWIN, M.D., C.M. Edin., has been reappointed Medical Officer of Health for Redditch.

OLDMAN, C. E., M.D. Camb., M.R.C.S., has been appointed Medical Officer of Health to the Godstone Rural Sanitary District.

PARTINGTON, WM., M.B., M.S. Glasg., has been appointed Medical Officer of Health for the Funstall Urban Sanitary District.

PERRY, S. HERBERT, M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

PHILLIPS, E. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the First Western Sanitary District of the Billesdon Union.

POCKLINGTON, E., M.R.C.S., has been reappointed Medical Officer of Health for Wimbledon.

PRICHARD, RICHD., M.D., M.S. Glasg., has been reappointed Medical Officer of Health for the Cardiff Rural Sanitary District.

PRITCHARD, E. L., M.B. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

SANDERSON, CHARLES, L.R.C.P. Edin., L.F.P.S. Glasg., has been reappointed Medical Officer of Health for Hastings.

SANDFORD, H. V., L.R.C.P. Lond., L.F.P.S. Glasg., has been reappointed Medical Officer of Health for the Rural Sanitary Districts of Bromyard, Hereford, Ledbury, Leominster, and Wesley Unions.

SHORTRIDGE, THOS. W., M.D. Brussels, L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health to the Honiton Town Council.

SMITH, T. W., L.S.A., has been appointed Assistant House Accoucheur to King's College Hospital.

SMITH, WM. R., M.B. Lond., M.R.C.S., L.R.C.P., L.S.A., has been appointed House Physician to King's College Hospital.

STEARNS, F. C., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Cottage Hospital, Walsall.

WALKER, H. STANLEY, M.B., C.M. Edin., has been appointed House Surgeon to the Dover Hospital and Dispensary.

WARNER, T., M.R.C.S., L.R.C.P., has been appointed Assistant House Physician to King's College Hospital.

WICKHAM, H. T., M.B., M.S. Edin., has been appointed Medical Officer for the No. 2 Sanitary District of the Newport Pagnell Union.

WILLIAMSON, A. S., M.B., M.S. Aberd., has been appointed Medical Officer of Health to the Sandal Local Board.

WILSON, A. C. I., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health to the Thurlstone Local Board.

WYNNE, W. A. S., M.D. St. And., M.R.C.S., has been reappointed Medical Officer of Health to the Lowestoft Urban and Port Sanitary Authority.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement.*

CANCER HOSPITAL (Free), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Board and residence, and allowance for washing provided. (Applications to the Secretary, 24, Finsbury-circus, E.C.)

## Births, Marriages and Deaths.

### BIRTHS.

BIETT.—On Sept. 24th, at Melbourne, Australia, the wife of J. Talbot Brett, L.H.C.P.L., M.R.C.S.E., of a daughter.  
 GIMBLETT.—On Nov. 6th, at Pembury-road, Clapton, N.E., the wife of W. H. Gimblett, L.R.C.P., of a daughter.  
 HAERIES.—On Oct. 30th, at Grosvenor House, Aberystwith, the Dr. T. D. Harries, M.R.C.P. Lond., F.R.C.S., of a son.  
 NICHOLS.—On Oct. 5th, at Secunderabad, India, the wife of Surgeon-Captain F. P. Nichols, M.B. Cantab., Army Medical Staff, of a son.  
 SCOTT.—On Nov. 5th, at Fitzwilliam-square, Dublin, the wife of J. Harrison Scott, F.R.C.S.I., of a daughter.  
 SCOTT.—On Nov. 1st, at Circus, Bath, the wife of Richard J. H. Scott, F.R.C.S., of a son.  
 WADE.—On Nov. 2nd, at Motra-place, Southampton, the wife of A. B. Wade, Esq., M.B., of a daughter.  
 WOODCOCK.—On Nov. 5th, at Springfield Hall, Wigan, the residence of her father, Wm Trevor Wauklyn, the wife of the late R. Fraser Woodcock, L.R.C.P., M.R.C.S., of a daughter.

### MARRIAGES.

BENSON—GABRIEL.—On Oct. 25th at St. Augustine's Church, Kilburn, Henry P. D'Arcy Benson, M.B., Ch.M., eldest son of the late Dr. J. E. Benson, of Queensland, Australia, to Mary Louisa Gabriel, daughter of the late John Gabriel, of Calne, Wilts.  
 COLLYNS—ABDIE.—On Oct. 19th, at the parish church of Abbot's Leigh, Robert John Collyns, L.R.C.P. and M.R.C.S., of Dulverton, to Eleanor Maud, youngest daughter of the late Henry Abbot, Esq., of The Priory, Abbot's Leigh, Bristol.  
 COWLEY—FULLER.—On Nov. 8th, at the Parish Church, Sutton, Surrey, John Selwyn Cowley, M.R.C.S., of Upton-on-Severn, to Lillian Fuller Fuller, younger daughter of the late Charles Fuller, of Halifax.  
 DICKINSON—EVENS.—On Nov. 3rd, at Holy Trinity Church, Sloane-street, Thomas Vincent Dickinson, M.D. Lond., oldest son of Thomas Dickinson, Esq., of Sloane-street, to Beatrice Frances Ayscott, youngest daughter of Captain Evens, late Royal Fusiliers, of Auber House, Clapham.  
 GEMMEL—THOMSON.—On Nov. 3rd, at B Ilhven Church, Kelvinside, Glasgow, Dr. Burns Gemmel, Liverpool, to Margaret Alice, eldest daughter of the late Dr. William Cooper Thomson, Glasgow.  
 JONES—EVANS.—On Nov. 2nd, at the Parish Church, Dowlish, by the Rev. W. R. Thomas M.A. (Oxon.) Vicar of Abersychan, assisted by the Rev. L. M. Williams, Rector of Dowlish, Samuel Cromwell Jones, M.D., B.S. (Lond.), of Merthyr, to Elizabeth Gwentlian, eldest daughter of John Evans, Esq., Iscoed, Merthyr.  
 KITSON—BURNSIDE.—On Nov. 5th, at St. Mary's Church, Beaminster, Dorset, Francis Parsons Kitson, M.R.C.S. and L.R.C.P. Lond., youngest son of the late Edward B-lamy Kitson, Esq., of The Lodge, Beaminster, to Beatrice Maud, youngest daughter of the late Col. Henry Edwd. Hillman Burnside, C.B., of Beaminster, Dorset.  
 ROGERS—CHURCHILL.—On Nov. 7th, at Bombay, Surgeon-Captain Frederick Arthur Rogers, D.S.O., Bengal Medical Service, son of the late Moses Rogers, Deputy-Inspector-General of Hospitals, Madras, to Janet Felicia, third daughter of John Churchill, of Wimbledon, Surrey.

### DEATHS.

CHRISTIE.—Nov. 4th, fallen asleep in Jesus, at Ash House, Broadgreen, aged 80 years, Thomas William Christie, B.A. Camb., M.R.C.S. Eng., for the past forty years a faithful preacher of the "Faith of God's Elect." "Happy art thou, O Israel. Who is like unto thee, O people saved by the Lord." Funeral at St. James's Cemetery, Tuesday, at noon.  
 LEAK.—On Nov. 4th, at his residence, Lawn Cottage, Over, Cheshire, Alexander Plozzi Leak, M.D. Aberdeen, aged 77.  
 MILLER.—On Oct. 28th, at Glasgow, Hugh Miller, M.D., C.M. Glasg., late of Hamilton-square, Birkenhead.  
 PITTS.—On Nov. 9th, at Capt Hall, Springfield, Chelmsford, Robert Zachæus Pitts, M.R.C.S., aged 42.  
 STEELE.—On Nov. 6th, at Guy's Hospital, John Charles Steele, M.D., Medical Superintendent, aged 71.  
 THOMSON.—On Oct. 30th, at Round-hill crescent, Brighton, James Archer Thomson, M.B., M.S., in his 49th year.

## Medical Diary for the ensuing Week.

Monday, November 14.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays, at the same hour.  
 ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations; daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M.; and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2 P.M.; Thursday, 2.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.; and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.  
 LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital: 1 P.M., Mr. R. Marcus Gunn: Affections of the Crystalline Lens.—101, Gt. Russell-st.: 3 P.M., Dr. Galloway: Genito-urinary Tract.—Parkes Museum (Margaret-st., W.): 4 P.M., Dr. L. C. Parkes: Hospitals.  
 THROAT HOSPITAL (Golden-sq.)—5 P.M. Dr. R. Norris Wolfenden: Laryngeal Neuroses.  
 MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. The President: Specimen of Old Dislocation of Ankle.—Dr. Percy Kidd: Tubercular Ulceration of Pharynx successfully treated by Lactic Acid.—Mr. Goodall: (1) Left Inguinal Colotomy for Pelvic Tumour; (2) Left Inguinal Colotomy, with subsequent Removal of part of the Rectum with the Growth, in a Man aged seventy.—Dr. Hadden: Urticaria Pigmentosa.—Mr. Hurry Fenwick: "Calsson" Work in Bladder Surgery.—Mr. Lockwood: Radical Cure of Hernia.—Mr. Turner: Bony Tumour of Pelvis associated with Rheumatoid Arthritis of the Hip.—Dr. Abraham: (1) Leprosy improving under Treatment; (2) Two cases of Skin Disease.—Dr. Herschell: Pulsatile Tumour of the Neck.—Mr. Sheild: (1) Cystic Tumour of the Aortic; (2) Early case of Raynaud's Disease.

Tuesday, November 15

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.  
 LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars: 4 P.M., Dr. Payne: Eczema, its Treatment.—Bethlem Hospital: 2 P.M., Dr. Theo. Hyslop: General Paralysis of the Insane.—101, Gt. Russell-st.: 3 P.M., Dr. Horman: Treatment of Bleeding Fibroids.  
 PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Special General Meeting to consider proposed alterations in By-laws. Ordinary Meeting. Dr. Sherrington: Colour Granules in Cells in Cholera &c.—Mr. J. Jackson Clarke: (1) Epithelioma of the Legs of a Hen; (2) Genito-urinary Organs of a pseudo-Hermaphrodite, with Capillary Urethra and symmetrically Sacculated Bladder.—Mr. C. F. Readles: Fibroma of the Male Breast. Card Specimen by Dr. E. C. Perry.

Wednesday, November 16

NATIONAL ORTHOPEDIC HOSPITAL.—Operations 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday and Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMUND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.  
 LONDON POST-GRADUATE COURSE.—Hospital for Consumption Brompton: 4 P.M., Dr. J. M. Bruce: Aneurysm of the Aorta.—Royal London Ophthalmic Hospital: 8 P.M., Mr. A. S. Mouton: Retinal Affections.  
 THROAT HOSPITAL (Golden-sq.)—5 P.M. Dr. Greville MacDonald: Laryngitis Acute and Chronic.  
 ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. F. Chapman: Feramifera of the Gault of Folkestone.—Mr. C. Haughton Gill: Fungoid Growths on Diatoms.—Mr. John Hood: Notops Ruber, a New Rotifer.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages and Deaths.

Thursday, November 17.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.  
 LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-street: 4 P.M., Dr. M. Lubbock: Bronchitis in Children.—National Hospital for the Paralysed and Epileptic: 2 P.M., Dr. Gowers: Cases in the Hospital.—London Throat Hospital, Gt. Portland-st.: 8 P.M., Dr. Woakes: Some Nasal Neuroses.—Central London Sick Asylum, Cleveland-st., W.: 5.30 P.M., Mr. Timothy Holmes: Surgical Cases in the Wards.  
 HARVEIAN SOCIETY.—8.30 P.M. Dr. Rayner Batten will exhibit and explain a new Clinical Pulse Manometer.—Mr. Buckston Browne: The Treatment of Impassable Stricture of the Urethra.—Dr. Charles Gross: Some Obscure Head Injuries.  
 NEUROLOGICAL SOCIETY OF LONDON (20, Hanover-sq.).—8.30 P.M. Dr. Head: The Distribution of Sensory Disturbances, with especial reference to the Pain of Visceral Disease.

Friday, November 18.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.  
 LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. J. M. Bruce: The Prognosis of Heart Disease.—Bacteriological Laboratory, King's College: 11 A.M. to 1 P.M., Professor Crookshank: Leprosy and Glanders (Sections).

Saturday, November 19.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.  
 LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr. H. Corner: General Paralysis of the Insane.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### MEDICAL AID ASSOCIATIONS.

WE have received a very large amount of additional correspondence on the subject of Medical Aid Associations, which by reason of the great pressure on our space this week we are reluctantly obliged to hold over for future consideration.

*Surgeon-Captain.*—We do not know any authority for the statement and we question if it be true.

*Dr. J. B. Ball.*—The paper will be inserted as soon as possible.

### "RELIGION v. CHARITY."

To the Editors of THE LANCET.

SIRS,—I think you are unjust to the Corporation of Dublin in your annotation headed as above. The corporation has not refused a grant to the Rotunda Hospital because there was not a majority of Roman Catholics on the board of the hospital, but because the authorities of the hospital systematically exclude Catholics from all the paid appointments and refuse adequate representation to Catholics on the board, though the vast majority of patients belong to that religion. It is also incorrect to say that the corporation gives grants to purely Catholic hospitals, like the Mater and St. Vincent's and refuses them to Protestant ones, such as the Adelaide. The latter is a purely sectarian institution, admitting no patients but Protestants. It is true the Mater and St. Vincent's are under Catholic management, but both admit freely patients of all denominations, and both from time to time have had Protestants on the staff and among the resident pupils. The Meath and City of Dublin Hospitals are as Protestant as the Mater and St. Vincent's are Catholic, and still receive grants from the Corporation. The injustice of this charge of bigotry against the Dublin Corporation will seem more evident when we remember the fact that it has just unanimously elected a Protestant to the office of Lord Mayor for the ensuing year, and that it pays considerably more than half its salaries to Protestant officers. If there is bigotry in the matter, it is certainly not on the side of the Corporation. Hoping you will insert this in justice to that much-maligned body,—I am, Sirs, yours truly,  
 November, 1892. L.M. ROTUNDA.

### NOTIFICATION OF SCARLET FEVER.

*F. Mallucis (Leicester)* asks:—

"Is it legal for the sanitary authority to decline to pay the fee for notification under the following circumstances?—B. sends a certificate that a child is suffering from scarlatina, and the patient is sent to the fever hospital and diagnosed by the medical officer of health as a case of measles and sent home. In a few days this patient is readmitted in a state of peeling, along with another child from the same house suffering from scarlet fever. B. was told that he would not receive a fee for the first certificate, but as a second case had happened he would be paid for the latter, which, he was informed, would come to the same thing, as only one certificate is required from the same house. You will see that if a second case had not occurred B. would not have received a fee at all. Is it not sufficient that the certificate should be to the best of his knowledge and belief?"

\*\* Notification in Leicester is not under the General Statute of 1849, and we have not the Leicester Corporation Act of 1870 before us; but if there be in that Act a limitation to the effect that second cases in the same house need not be notified it is obvious that the fee in this case is due for the first, not the second, case reported. But the instance goes to show that the advice given by the Local Government Board to the effect that fees should not be withheld on the ground of assumed faulty diagnosis, and only when distinct *mala fides* is in question, is the right one.—ED. L.

*Medical Witness.*—1. The operation ought not to have been performed. 2. The father could have sued. In the absence of the parents or guardians the surgeon assumes full responsibility. In their presence he cannot usurp it.

*M.D.*—St. Andrews or Durham, probably the former.

### A GROWING EVIL.

To the Editors of THE LANCET.

SIRS,—Among the various annoyances which beset the medical man that caused by impostors who mimic the science of medicine and surgery is by no means the least. Is it not preposterous that this country is the only one in Europe where any rogue may put up a brass plate and advertise to all the world that he sees patients between such-and-such hours daily, and that he alone has a sovereign remedy for every complaint under the sun? I do not advocate that the law should be carried to the extreme that we find it to be the case in France and Switzerland, but I am sure both the profession and the public would be the gainers if it were made an offence for anyone to receive money for medical advice whose name did not appear on the Medical Register.

Only the other day I was accosted by a man in Indian costume near Madame Tussaud's, who presented me with a flaming handbill announcing that X—, the great Indian doctor, was prepared to cure all kinds of diseases of the eye by means of marvellous Indian herbs. A little further on the same road, towards Euston Station, I noticed the "Ophthalmic Institution," presided over by a man named Pomies, who professes to cure every eye disease, from cataract to glaucoma, by means of "golden ointment" and "drops." Retracing my steps on the same road, I came to Bell-street, Edgware-road, and there I beheld one of my dispensary patients coming out of a public-house rejoicing in the name of "The Green Man." On venturing to ask her what benefit she expected to obtain from the gentleman in green, she informed me that she went there for medicine for her little boy. Further inquiry brought to light the strange fact that the former proprietor of the "alcohol dispensary" had left a sum of money in her will to be expended in eye lotions and drops to be given away to any person suffering from inflamed eye or defective sight, backed up, I suppose, by copious libations of beer and spirits, which were not included in the free bill of fare.

Now, Sirs, I ask you, Is it right that poor and ignorant women and children should be allowed to be ensnared into these pitfalls, so that their diseases, which in proper hands could be nipped in the bud, should be permitted to reach a stage beyond the skill of science? We cannot hope that the public should have discernment enough to see from *a priori* considerations why the professor in the Euston-road must only lead to disappointment by promising to clear a cataractous lens by means of eye lotions and electric currents. We cannot hope to convince the patrons of "The Green Man" that the gentleman behind the bar who dispenses alcohols of various strengths in media of many hues should not be the most suitable person in the world to treat an incipient glaucoma by means of drops and lotions; but what I do hold is that the public should be protected from such snares, especially that every square mile in London contains at least one free hospital or dispensary conducted on rational principles. Years ago the present Prime Minister declared that the object of all legislation was to make it easy for men to do right and difficult for them to do wrong, and surely it is only another way of stating Lord Beaconsfield's celebrated paraphrase of the preacher, "Sanitas sanitatis omnia sanitas," by saying the object of legislation is to make it easy for men to keep well and difficult for them to get ill. May I urge, Sirs, that the time is more than ripe when Parliament should interfere to protect our rights as well as the public from imposture?

I am, Sirs, yours truly,

G. LINDSAY JOHNSON, M.D., F.R.C.S.

Stratford place, W., Nov. 1st, 1892.

## RETROGRADE PHYSIOLOGY.

Dr. F. JEZEK of Berlin is a bold man. He claims to have proved that the great physiological tenet incontestably, as we have all thought, demonstrated by William Harvey is untrue. In a monograph which leaves little to be desired in the way of typography and paper he demolishes—to his own satisfaction—the doctrine of the circulation of the blood with the heart as its central motive power. The title of this revolutionary brochure is pithy and suggestive. It runs: "Umsturz der Harvey'schen Lehre vom Blutkreislaufe und Erklärung der Natürlichen Blutbörgung." (Leipsic: P. Hobbings, 1892.) Dr. Jezek's plan of campaign against the physiological stronghold opens with a refutation (?) of the statement that when large arteries are occluded the circulation is carried on by collateral channels. At any rate, in one dog in which he ligatured the brachial, femoral, and carotid arteries on both sides, and in another, the abdominal aorta, without more than temporary disturbance, he failed to find by injection and dissection, two months subsequently, any enlargement of collateral vessels. He next proceeds to examine the condition of the heart during life by means of direct palpation, and declares that he could detect no periodical change of volume (diastole and systole). Next he compares the blood pressure in heart and vessels with the pressure of the air in the lungs, and exhibits synchronic tracings to prove that the intra-vascular and intra-pulmonary pressure correspond with regularity, the periods of minimal and maximal pressure coinciding in each. He claims also by the same method to show that the ventricular pressure corresponds with the auricular, and both with the arterial and venous. Those results traverse in a singular manner those of most observers, although Dr. Jezek thinks that some are of the same opinion as himself. Of course he does not ignore the minor variations of intra-cardial pressure that occur between the respiratory waves and which, according to him, by no means correspond with the systole. Well may he claim, if his inference were only true, that such a conclusion is opposed to "Harvey's theory." Next he dismisses the notion that the heart acts like a pump by reference to the phenomena of double heart beat and of the pulsus bigeminus; and he maintains that the cardiac contractions are not due to stimulation of the ganglia alone, but to direct stimulation of muscle fibres, the contraction of which is not sufficient to exert any notable influence on the change of the heart's volume. He further cites malformations of the heart—such as single auricles, aorta springing from both ventricles, absence of pulmonary arteries—as evidence against the ordinary acceptance of the cardiac action. "What, then, does he substitute for this iconoclastic destruction of prevailing doctrine? Briefly put, his theory is that the condition of the lung during inspiration and expiration respectively causes an alternating diminution and increase of the calibre of the pulmonary vessels, so that the blood is pressed into the left side of the heart and the systemic arteries from the air-distended lung. Simultaneously there is a rise in pressure on the venous side, which causes the blood to flow into the lungs as they shrink during expiration. All this is so exactly contrary to known facts of the influence of respiration on the venous circulation that it is difficult to see how it can be seriously held, as it is by Dr. Jezek, who furnishes several diagrams, cleverly devised, to support his views of the main factor in the circulation being the changes in the form of the lungs. Nay, he discards the term "circulation" altogether, and considers that the blood simply flows backwards and forwards, according as it is drawn into or pressed out of the lungs. We are fain to rub our eyes and marvel whether we are not living in the days of Galen, at teaching so primitive, which he manages to fit into a theory of the pulse and of the impulse of the heart in a way that is even more singular. In his own words, he claims to have proved that the cause of the pulse wave does not depend on the action of the heart, but on the difference in pressure due to the periodical diminution and increase of the diameter of vessels; and that the heart which does not have the power ascribed to it is merely passively distended and relaxed by the changes in the tension of the blood column. He promises a further contribution on the subject with respect to digestion, but we frankly confess to a doubt whether anyone will take the trouble to refute his refutation of a well-established doctrine.

*Antiquarian.*—Our correspondent justly resents having it said that he "covers" an unqualified assistant in a dispensary connected with which handbills are issued. He attributes this erroneous statement to medical men. We hope he is wrong here. At any rate, we fully accept this disclaimer, and we do not see that he need make it in the newspapers. Let him trace the error to its source and demand its contradiction.

*L.*—The card should be enclosed. The information is of an essentially private and professional character.

## TREATMENT OF DIPHTHERIA.

*Dr. Emanuel May* writes advocating the early and thorough application by the brush to the affected parts of the throat in diphtheria of liq. hydrarg. perchloridi, or strong solution of argent nit. (3i to ʒi), or the tinct. ferri perchloridi. He has found that many object to such applications, preferring sprays of boracic acid or similar mild measures, which he much deprecates.

*M.R.C.S., J.R.C.P.*—Similar cases of acute orchitis following influenza are to be found in our columns—viz., Jan. 2nd, 1892 (p. 22), by Mr. J. W. Harris; Jan. 23rd, 1892 (p. 193), by Mr. J. E. Briscoe; Feb. 13th, 1892 (p. 359), by Dr. Gordon Kelly. In the report of the Berlin Society's Committee it is stated that there were records of twenty-five cases of epididymitis and orchitis given in 3185 returns.

*Mr. C. French Hensley* (Broadway).—Our correspondent thinks that such expressions as "infamous Vaccination Acts," "greatest fools," "filthy dogma" and "revolting quackery" are useful as arguments against compulsory vaccination. These terms are not dignified, reasonable or true. In other portions of his communication the language is hardly courteous.

*Lieut.-Colonel Donegan.*—We are acquainted with no institution in Great Britain or Ireland which admits male and female students to all the classes included in a medical curriculum.

*Enquiry* has not enclosed his card.

## A COMPLAINT.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged by your finding space for the following—viz.: In March, 1889, Messrs. — and Co. sent instruments to Winton for display. I selected some and paid for them in full, five days later, taking note of the items on counterfoil of cheque. Some time afterwards applications for payment and threats of legal proceedings began to pour in, notwithstanding that I wrote on three occasions asking for items, saying I had paid, and requesting the annoyance might cease. Finally, this month, a summons to the London City Court was thrust into my hand in the street. I at once gave "notice of intention to defend," asked again for particulars, and was at last vouchsafed this: "'89, Apl. 24th. To goods [sic], 38s. 6d. '89, Apl. 20th. Cr. by returns [sic], 22s." (N.B.—My cheque and *their receipt* was for 31s. in March!); and ten days before the time fixed for hearing the action I received notice from Messrs. —'s solicitor that "all further proceedings in this action are wholly abandoned." Not a word of apology or regret from the firm for subjecting me to this most groundless and vexatious action!

I am, Sirs, yours faithfully,

W. MORTON HARMAN, B.A., M.D., F.R.C.S.I.  
Christchurch-road, Winchester, Oct. 31st, 1892.

## "EFFICIENT VACCINATION."

To the Editors of THE LANCET.

SIRS,—I can fully endorse the statements made by "Public Vaccinator" as to the inefficient manner in which the operation of vaccination is performed by a great majority of private practitioners. In my district the operation is not only inefficiently performed, but a certain practitioner and his assistant, after making themselves acquainted with the births that have taken place, are actually in the habit of vaccinating all children of the poorer classes gratis, apparently for the express purpose of preventing them being taken to the public vaccinator, where the operation is performed *secundum artem* and under Government supervision. Until some standard of efficiency is strictly demanded from all practitioners alike the beneficent discovery of Jenner is likely to fall more and more into disrepute.

I am, Sirs, yours faithfully,

October, 1892.

ANOTHER PUBLIC VACCINATOR.

## "THE HISTORY OF QUACKS AND QUACKERY."

To the Editors of THE LANCET.

SIRS,—Referring to the statement in "Chambers's Etymological Dictionary" (quoted by your correspondent, Dr. Leonard Kidd) that the word "quack" is derived from the cry of the duck, it is a curious fact that the Egyptian hieroglyphic for a doctor is a duck.

I am, Sirs, yours obediently,

Nov. 7th, 1892.

R. M.

## INTRA-THORACIC AUSCULTATION.

To the Editors of THE LANCET.

SIRS,—I think a reference to the "Medical Digest," Section 838: 3, will show that the method so graphically described by Dr. Richardson at page 1037 was somewhat similarly described by Bianchi in 1838 and Giorgeri in 1839. The concluding sentence of Giorgeri's paper runs thus: "He believed that endo-auscultation may prove of great service in the study of diseases of the stomach and œsophagus, and possibly of the circulatory system in the thorax."

I am, Sirs, yours truly,

Boundary-rd., N.W., Nov. 6th, 1892. RICHARD NEALE, M.D. Lond.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—

- A.—Messrs. Allen and Hanburys, London; Mr. W. Innes Addison, Glasgow; Alpha, London; Albion Soap Co.; Anxious; Antiquarian.
- B.—Dr. Robt. Boxall, London; Mr. Thos. Bernheim, London; Dr. Bond, London; Mr. Botwood, Ipswich; Mr. Bruerton, South Norwood; Messrs. Benson and Co., Wigan; Mr. Burke, Wolverhampton; Mr. Bush, Weymouth; Mr. Bontley, Whitehouse; Mr. Bellars, Leicester.
- C.—Prof. W. W. Cheyne, London; Dr. W. S. Colman, London; Dr. Harry Campbell, London; Mr. E. Clochnitts, Ingateston; Messrs. Crossley, Moir, and Co., London; Mr. Cornish, London; Carriage Insurance Co., London; Cortland Carriage Works, London
- D.—Dr. E. Davies, Wrexham; Mr. Ed. Duke, St. Leonards; Lieut.-Col J. H. Donegan, Conk; Mr. Duncan, Salop
- E.—Dr. George Elder, Nottingham; Ebor, London.
- F.—Mr. Fegan, Brandon; F.R.C.S.E.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

# VERITAS PREVALEBIT.

## EXTRACTUM MALTI (KEPLER).

THE Extract of Malt prepared according to the Kepler process is always uniform and reliable and obtained from the finest Malted Barley only. The introduction of the Kepler process marked a distinct advance in the method of preparing this valuable digestive and nutritive agent; since still further progress has been made in the path of improvements, and the Malt Extract (Kepler), as issued to-day, represents fully all the valuable constituents to be found in malted grain — the Albuminoids, the Natural Phosphates, Maltose, Dextrine, and the important amyolytic ferment, Diastase. The Kepler Extract of Malt is not in any sense a fermented product; its nutritive properties are not sacrificed to the formation of ethylic alcohol, and the greatest precaution is observed that the heat employed shall not ruin the diastase, or destroy the albuminoids by coagulation. As a food in itself, as an invaluable aid to the digestion of other aliments, the popularity of the Kepler Extract of Malt is in itself a proof positive of its value and efficiency.

As an instructive commentary upon what has been already said above, the following paragraph, taken from "Braithwaite's Retrospect of Medicine" for January to June, 1892, is interesting:—

"KEPLER EXTRACT OF MALT.—During the past year the value of Kepler Extract of Malt has been more generally recognised and its use has greatly increased. It was found particularly valuable in the convalescent stages of influenza, and was often relished and digested when no other food could be retained. Many practitioners found it to be their sheet anchor, and would have been in despair but

for its assistance. In some of the severest cases in which it was given the patient rapidly recovered and returned to his work with none of the weakness and depression which was felt by many persons who had not had the advantage of taking it. The manufacturers of Kepler Extract have recently introduced a much thinner preparation, *Essentia Malti*, clear and thin like the finest virgin honey. This was to overcome the objection some invalids made to the thick and sticky Kepler Extract, and in many cases it has been relished and been found most useful. A great future undoubtedly awaits both preparations, which have a distinct rôle to play, and which cannot be superseded by beer or any of the many fermented preparations of malt."

The following useful combinations are also issued in the same sizes as the simple extract:—

Kepler Extract of Malt with Beef and Iron.	Kepler Extract of Malt with Iron and Quinine Cit.
Ditto with Cascara Sagrada.	Ditto with Iron, Quinine and Strych.
Ditto with Castor Oil ("Malto-Ricine").	Ditto with Hops.
Ditto with Cod Liver Oil (Kepler Solution).	Ditto with Hypophosphites.
Ditto with Cod Liver Oil and Ferrous Iodide.	Ditto with Pancreatin.
Ditto with Cod Liver Oil and Hypophosphites.	Ditto with Pepsin.
Ditto with Chocolate.	Ditto with Pepsin and creatin.
Ditto with Ferrous Iodide.	Ditto with Phosphates (Chemical Food).
Ditto with Iron Pyrophosphate.	Ditto with Phosphorus.
	Ditto with Peptones.

The Kepler Malt Extract is supplied to the Medical Profession in bottles of  $\frac{3}{4}$  lb. and  $1\frac{1}{2}$  lb., at 1s 8d. and 3s. each. Retail 2s. 6d. and 4s. Prices of the combinations vary according to the formula.

(REGISTERED).

"Maltine contains all the valuable materials that it is possible to extract from either malted barley, malted wheat, or malted oats."—Prof. ATTFIELD.

"Maltine exhibits in an eminent degree the starch-dissolving power of diastase."—THE LANCET.

"The greater nutritive value of this combination is apparent. Clinical experience enables us to recommend it in virtue of its albuminoid contents and its richness in phosphates and diastase."—BRITISH MEDICAL JOURNAL.

"As regards diastase, Maltine is far superior to the best extracts of malt I have ever seen. The nitrogenous substances in Maltine are richer than in any other extract of malt."—STUTZER.

"Its flavour and odour are those of a delicious sweetmeat."—ATTFIELD.

"Its consistence is most convenient."—BRITISH MEDICAL JOURNAL.

Maltine obtained the only Gold Medal for Extract of Malt at the International Health Exhibition, London, 1884.

## THE IDEAL PREPARATION OF COD LIVER OIL.

Cod Liver Oil has been shown to be the most effective agent in counteracting phthisical disease.

"We know that if we can manage to enable a patient with pulmonary phthisis to digest and assimilate cod liver oil, tissue nutrition becomes so altered that the development of tubercle is usually arrested" (Dr. MILNER FOTHERGILL). But cod liver oil is difficult of digestion. Many patients cannot tolerate it, and with others it passes through the bowels undigested. The nausea and acid eructations that follow its ingestion are one of the everyday difficulties that beset the practising physician. The success with which these difficulties have been overcome in "Maltine with Cod Liver Oil" is, we are glad to say, fully appreciated by the Medical Profession. In this preparation the purest cod liver oil is combined with

"Maltine," that is both a most nutritious food and exceptionally rich in the digestive ferments. Its taste and flavour are delicious, and its convenient consistence renders it easy to administer and facilitates its absorption. By reason of the special and improved process of blending the oil with the malt, the oil globules are in a finer state of subdivision than those of the fat of milk. The oil is thus in a condition to be at once acted upon by the pancreatic ferments and immediately absorbed. The "Maltine" *preserves the oil from change* by the gastric secretion in its passage through the stomach. Maltine with Cod Liver Oil does not give rise to acid eructations; and the taste of the oil being completely disguised by this mode of exhibition, it never occasions nausea and is successfully administered to the most fastidious.

"Patients unable to tolerate the purest and most carefully prepared Cod Liver Oil can readily digest and assimilate it when combined with MALTINE."—BRITISH MEDICAL JOURNAL.

"Fulfills all the conditions necessary for perfect digestion. An elegant and palatable preparation."—MEDICAL PRESS AND CIRCULAR.

## MALTINE WITH CASCARA SAGRADA.

The value of Cascara Sagrada in obstinate and habitual constipation has been proved in numberless instances. The popularity of the drug as a gentle and convenient laxative has grown apace despite its somewhat bitter and unpleasant taste. In combination, however, with Maltine this latter objection is almost entirely disposed of. A fluid ounce of Maltine is combined with a drachm and a half of Cascara Sagrada, and in this preparation the drug is presented in a most agreeable and suitable form. Apart from its usefulness in the case of adults, authorities affirm that Cascara Sagrada is also of much value in habitual constipation in infants and children.

## MALTINE COMPOUNDS.

MALTINE WITH LIME.  
MALTINE WITH CARRAGEEN.  
MALTINE WITH IRON.  
MALTINE WITH COD LIVER OIL.  
MALTINE WITH EASTON'S SYRUP.  
MALTINE WITH PHOSPHATE OF IRON & QUININE.

MALTINE WITH ALTERNATIVES.  
MALTINE WITH PHOSPHORUS.  
MALTINE WITH PHOSPHORUS COMPOUND.  
MALTINE WINE.  
MALTINE WITH PEPSINE AND PANCREATINE.  
MALTINE WITH CASCARA SAGRADA.

SAMPLES FREE TO MEDICAL MEN. IN PRESCRIBING, KINDLY SPECIFY—"MALTINE CO."

## An Address

ON THE

## RELATIONS OF MEDICAL MEN TO SOCIETY.

*Delivered at the Opening of the York Medical Society,  
Oct. 12th, 1892,*BY PROFESSOR CLIFFORD ALLBUTT,  
M.D. CANTAB., F.R.C.P., F.R.S. &c.

MR. PRESIDENT AND GENTLEMEN,—One who has passed middle life in a laborious calling may gradually become aware of a certain sense of satiety—a sense of weariness and detachment of interest, so that the work of life becomes tedious, and curiosity and adventure fail or follow after other things. Thus such an one becomes rather oppressed by the limits than inspired by the opportunities of his art, and, losing the faith and the buoyancy of earlier days, he tends to fall into a routine of thought and into a fixity of practice. Dissatisfied with himself for these things and fearing that his faculties are touched by the cold hand of time, he dreams of retirement, either for his own comfort or for conscience' sake. Again, a man of fifty years of age, if he be not a teacher, is losing touch with young men; his friends are old friends, his friends' children, away at school or university, are strangers to him; thus he is deprived of the rekindling which the young give to the elder. The very rashness, the impulsive and untutored fancy, the brave disregard of labour and danger and of the complexities of things, the superb indomitable confidence of young men counteract the rigidity and the worldly wisdom which fasten upon ageing men and tend to sterilise them. Their due fermentations slacken for lack of those microbes. Such was my experience when, owing to a rule which I venture to think an unwise one, I was removed from the active staff of my hospital at the age of forty-seven—an age when vigour is yet full and experience ripe. The relief of the first few weeks of my vacation soon palled; I began to miss the young faces which were wont to gather about me, the heaviness born of long toil settled down upon me, and I began to see in my work the dulness of a trade and the dangers of cupidity. Four years later I took the occasion of a change in the conditions of my calling which altered the sphere and the character of my work, and for nearly three years I enjoyed the holiday of a new vocation and a new studentship. When, after this complete and refreshing change, I was at the beginning of this year called back to the practice of medicine, and to this again in association with a great school, I felt, as it were, born again and endowed with a rare blessing—the blessing of entering upon my profession with the ardour of earlier years, but without their cares and their errors. Is it egotistical in me thus to speak of my own feelings and experience to-day when I find myself, by your generous invitation, here in York again—a centre of so much of my past practice, the home of so many of my friends and fellow workers? I trust not; I rely upon your forbearance and your sympathy. I come back this evening not only with energies renewed, but also with a larger knowledge—a knowledge extended in a department of medicine which is too often hidden away from the common observation, even of practising physicians. Of this experience I may have much to say as occasion serves, and something to say this evening.

Your courteous secretary, when he conveyed to me your welcome and honourable invitation, told me that my audience would not be exclusively medical, and he suggested to me that my address should deal with a subject of general interest to society. I replied, and it was agreed between us, that I could not do better than take this very suggestion for my discourse and consider the relations that exist, and should exist, between medical men and society at large; the place and function which we have in the body of the State. In respect of the existence of the State our function is a subordinate one. Whether in a rudimentary stage or in stages of fuller civilisation, the existence of the State depends upon men of war. These men, so far as we can foresee, must always be the most necessary of our members and will be the most honoured, for in times of danger they

must lead, and at all times we see that the art of war is the art of peace. Again, if society, thus preserved, is to have internal stability and cohesion it must be ruled by custom and public and private law; as the soldier makes for external peace, so must we try to regard the lawyer as the minister of internal peace. Until a society be secure without and within it can have no leisure to seek after the higher ends of life, nor to hearken to the voices which awaken the higher passions or lead to the deeper moods of contemplation. Society must then first exist and in the next place learn to what main ends it exists, before the bodily health of its members come into question. Indeed, as the higher purposes of life spread themselves before his imagination, a certain noble indifference to personal ease and longevity becomes the good citizen. We, then, who administer this sort of consolation must be content to take a somewhat lower place in a great nation, unless we can show a title to partake in a task higher than the mere conservation of bodily health, whether of individuals or of communities. We must not forget that the attainment of the most brilliant periods of illustrious nations has been quite compatible with indifference to the sewage question, and that great citizens have preferred glorious life to long life and self-devotion to eupepsia. Even in a state of society so steadfast as our own there is something not heroic in the mere health-hunter, in the man who wanders from doctor to doctor, and from land to land, not that he may do his duty the better, but that he may bear an ache the less. It is our business no doubt to minister to his demands; it is our duty to unfold the last roseleaf which lies awry under his loins, as it is our pains to pick out the last pea which lurks under the downy bed of the princess, for only by her discovery of the pea do we know her to be a real princess; yet there lie in our hearts the names of those, many, many of them our own brethren, who, sturdily thrusting down the knowledge that their weak bodies were playing them false, laboured on to the end.

We will not claim too high a place for our craft lest we be punished for our self-esteem; yet to the physician whose unseemly privilege it is to preserve a great leader or a great seer for the service of the State, or, in the life of the family, to restore the loved to the loving, and to bind again the bond which death would have dissolved, there is no light honour, no small blessing; nor is it a small thing, passing beyond personal service, to restore to health the tainted life of a community of men, to purify the wells of life or to arrest the march of a pestilence. But we bear a greater testimony than these. Is there not something more than the cure of disease, something more than purification, something even more than the defeat of a pestilence to which we bear witness? Amid the conflict of religious sects, amid the decay of creeds, even beyond righteousness itself, is there not arising a new idea of humanity—of ethics springing rather from mutual sympathy and tenderness than from moral codes or supernatural sanctions? Are not our eyes opening to see in this humanity, in the revelation of that higher life which is found by losing ourselves in others, the essence of the gospel of Christianity; and if we are true to the best work of our calling, are we not ministers of this new and fruitful hope? To regard the individual conscience is to regard a dark, an unstable, even a whimsical, standard; but to form from day to day higher and higher conceptions of human ideals and of human service is to set forth and to strengthen the ethics of the future, and to this work we also are called. We are concerned more or less directly in the solution of many social problems which may be solved this way or that, but the issues of which are of grave consequence to ourselves and to our children, and will bear good or evil as they come into accord with the higher or the lower impulses and tendencies of modern civilisation. For example, how are we to deal with our insane, our poor, or our criminal members; with diseased, maimed, or idiotic children? Is it reasonable, in order to secure the survival of the fittest, that lunatics should be suppressed, criminals hanged, idiots and cripples gently drowned and hopeless sufferers poisoned? I will not venture to deny that such customs may be essential to the existence of a tribe of Red Indians, and in them may even be compatible with certain lofty virtues, personal or tribal—nay, I will not deny that even infanticide may be practised and approved in certain states of certain societies, but we shall all agree that such customs are to be regarded as of provisional utility. In a rude society the preservation of bare existence must be the dominant claim; we, however, are set free for a more perfect service; what shall our course of action be? Take the case of a murderer arraigned before society for his deed; the soldier or the

lawyer has to regard the matter as one of the immediate safety of society; and under all circumstances the mind of either will be turned simply to the suppression of the malefactor. Carlyle, in one of the Latter Day Pamphlets, seriously proposed to deal with vagrants by flogging in the first instance, and in the next, if the first correction failed, by shooting them. Yet have not members of our profession in courts of law withstood not arguments only, but also derision, when in certain cases they set forth the phenomena of homicidal mania, of epileptic violence, of delusions leading to crime and so forth, and have nevertheless slowly but surely driven the lawyer to restrain his hands, possibly even to modify his opinions? And to what end? Who can say that persons subject to homicidal mania or epileptic fury are not better put to death, both for the safety of society and for their own peace? Fierce and predatory instincts are none the less dangerous for being ingrained; in so far, indeed, as they obey strange and incalculable motives are they not the more dangerous? So when a habitual criminal, a thief or a vagrant, is brought before the magistrate, has not the sociologist to look beyond the immediate duty of the court and to consider whether the aberrancy be not even an untimely virtue?—"l'humanité a commencé tout entière par le crime";—or, if otherwise, whether the fault be in the action, positive or negative, of the older and more fixed organs of brain or body which no ordinary outer motive can change; or, again, whether it be due to the action of those more recent and loosely organised parts of the nervous system for the state of which we are called responsible, and which, at any rate, are constantly under modification by outer motives—such, for instance, as rewards and punishments? Nor is the question of responsibility exhausted even by these considerations; for if crime or wickedness be not the result of fixed forms of growth in the individual, but rather of modifiable parts, we have still to ask whether the causes of the discord be not due to conditions of external life for which society, rather than the individual, is responsible. For in reason society may not punish evil doers of its own making.

Again, who, taking his seat, as I have often done, in the wards of an idiot asylum, and, watching the antics of these pitiful, grotesque and degraded creatures, has failed to ask himself to what end they are cherished or even kept alive? Would it not be better that many of them, at any rate, should be consigned to a lethal chamber? Perhaps more hardly still presses upon us the question of suicide. There is no doubt some unreality about the complaints of many sufferers from melancholia, an unreality often hard to measure; but there is as little doubt that the horror of life is grim and abiding enough in many of them. A thoughtful woman lately denounced to me somewhat bitterly the cruelty in a system which has condemned a near relative of her own to confinement for twenty years or more, merely because he desires to end a life which is a hideous torture to him, and thus compels him to bear the burden of it. And who is to say that the reply to her and to him is an easy one? Once more. Beside the bed of one suffering from incurable pain—from aneurysm be it or cancer—who has not asked himself to what purpose that woful life is tenaciously spun out by every art that physician and nurse can devise, despite perhaps the longings of the sufferer himself to be at rest?

These are some of the more grievous kinds of stress which try us, but I need scarcely point out that within these outer limits are a large number of cases which lie open to similar arguments and to similar doubts, and which involve practical difficulties which we are called upon to consider and even to resolve either on grounds of private expediency or of public policy. For instance, should persons who inherit disease of mind or body, or even a disposition to such disease, be permitted to marry? To what degree should children be subject to their parents, and what in them are the respective claims of discipline and education on the one hand and of gaiety and freedom on the other? What are the evils, to body, mind or affections, of gathering stray children together in institutions, and how are these evils to be avoided? Is the gain of any social fashion, system, party or creed which tends to steady us and to keep us together, greater than the harm done by it in the loss of individual liberty and sincerity? Such questions are almost endless, and, as churchmen lose hold or lose courage in these matters, they come more and more into our hands: thus we become more and more concerned not only with the growth of the lower body—of the bones and the blood with their affections and lusts; but also with the growth of the higher body—of the organs of the

mind and of the imagination. Common sense, good guide as it is in common affairs, takes no account of new ideas. The robust sagacity of statesmen and lawyers, which is bred of incessant converse with practical life, is perhaps the best instrument we can have for the ordinary courses of law and politics. But this mental habit—the mind of the clubs as we may call it—is too blunt and rigid to handle new ideas or even to perceive them. Men who find their scheme of life workable have no desire to transcend it. The man of the world, as I have said, may think of the epileptic homicide that, explain him as you may, so wild a beast is better put to death, both for our sakes and his own. Indeed, what gain can it be to him to be spared for lifelong detention in Broadmoor? Thus again, of criminals of fixed type, the sensible man thinks that were flogging more freely dealt out to brutal offenders we should have fewer brutal crimes, and that no such punishment can brutalise men who are brutes already. Here, however, we touch the region of new ideas, and here common sense is at a loss. For the question arises, not whether the homicide be the worse, or the criminal brutalised, but whether any such kind of treatment brutalises those who contemplate it, or arrests in them the growing sense of the sanctity of life; the question is not so much of its direct relation to the individual as of its recoil upon society. So long as the public find no offence in this kind of justice so long it may be excellent justice; but so soon as the public comes to perceive that it is rough justice it will tend to violate the higher sentiments, and grow mischievous less to the sufferer than to those consenting to his fate. In this view the individual is not forgotten, or his deserts, but, as has been well said, Ugolino awakens in the reader far more of pity for his cruel death than of loathing for the crimes which that death was insufficient to expiate. Not that the individual is more than the civic life—quite the contrary; it is that a broadening and deepening of the fund of pity is a condition of the higher forms of civic life. Common-sense used to declare that men whose hands are strong, but whose heads are thick, may well be the slaves of men of finer clay; yet the old world and the new have been rent by this high argument, and the issue has been decided against common sense, or against that which then was common sense. Henceforth all nations proclaim not only that life, as life, must be cherished, but that the opportunities of life shall be safeguarded also. Freedom shall mean not only the abolition of formal slavery, but also the removal of all hindrance to physical and moral development. This faith, this tender reverence for life and its opportunities, men of our profession have unselfishly and persistently preached and proved, hoping in due time, perhaps, to reach the moral elevation of the Bishop of Manchester.

Our appeal to those in authority, then, shall always be this: Will this dispensation tend to increase or to diminish the fund of pity? Men of the day, loyal public servants, men of uprightness and of clear and narrow vision, are hardly moved by new ideas; but new ideas, like mushrooms springing underground, are irresistible, and are apt to become destructive if resistance be continued. The duty of society towards suicides is more difficult to define. "Their temporal offence," in Blackstone's words, "is committed against the king, who hath an interest in the preservation of his subjects"; or, in the language I have used to-day, they cheapen life which it is our duty to consecrate to civic service only. Life shall not be expended for personal ends; or even for mere personal honour, which is apt to be fantastic; or for personal relief, which is desperation. Despair, however, may hold a man as a disease, and in this case shall we connive at suicide? In this matter connivance or even supineness is consent. On the other hand, if we are to dog every man who at any recent time has been heard to call for death, we shall do much wrong, and some wrong of this kind is done. The sacredness of life will not, I think, be diminished if on such a death we can show that precautions of reasonable amplitude had been taken. It is not for us, or for superintendents of asylums, to make suicide impossible at the cost of all who are dejected in spirit. We shall not thus increase the general fund of pity.

In the matter of "euthanasia" our course is clearer: the cases in which a sufferer, not sick of mind, calls instantly and persistently for relief by death are fewer than we are wont to suppose; whereas the cases in which that relief of his would bring solace to the bystanders are many. As Jeremy Taylor says, "A healthless body and a sad disease do seldom make a man weary of this world, but still he would fain find an excuse to live." Herein the broad rule

shall hold, that life shall be laid down only in civic service, and he shall bequeath to his children the noble example of his patience. That which I have spoken concerning the sanctity of life itself I have said also concerning its freedom. By freedom, however, I mean not mere licence, but opportunity: the man who is merely cast loose is not the most free, but he whose higher aims and special faculties have the most space and encouragement. There is a natural tendency in us—the original sin of our craft—to take too carnal a view of the body. At what cost, we cry, are these weakly children nurtured; to what end are these channels of disease—scrofula be it, cancer or neurosis—kept open? Shall we not favour the survival of the fittest?—who, then, are these weaklings to whom we give footing in our room? Now the survival of the fittest may or may not be the survival of the highest. The fittest of a backward or retrogressive society would not be the best of our own. We cannot tell which shall be the fittest till the form of the coming time is revealed. A society at one time may need bone and muscle, at another may dispense with some of its prize-fighters and need the qualities of the inner life. It is now far more to our people that the fund of pity should increase than that all weaklings should be eliminated. Tenderness, gratitude, love are more to us than two legs, two arms or two lungs; moreover, the higher gifts of the imagination may be found in the frailest or the humblest vessels. What would have been our loss had the parents of Keats or of the Lambs been forbidden to marry by the common order of medical men to forbid the unions which may produce such children? Nay, even Mr. Dick had a kind of wisdom which many reasonable men fail to attain. The highest works of man are no doubt the sanest; the most perfect is the most serene; in the strongest is strength most concealed; yet how much the poorer would the world have been without the noble melancholy, the lyrical vision, the weird romance, the Elian humour and sympathy, the passion or the fiery enthusiasm of many of those whose names the world will not willingly let die, but whose minds were darkened by the shadow of insanity. What are we, then, to do? Are we to drift and to let the weak and unstable increase as they may? Not so. In the first place, we must so watchfully govern the conditions of life that the weak shall be made strong and the crooked straight; and in the second place, as we advise under the special circumstances of each case, we shall modestly remember that there is more in philosophy than our doctrine, more in mutual affinities and spiritual impulses than we can analyse or direct. This is in the manner of the higher part which I have claimed for our profession in the time coming and now at hand.

In claiming for our profession a part higher than to minister to the grosser functions I have been bold, but my note is no bolder than that tonic of our brotherhood—the oath “which in its grandeur and simplicity, and in the deeply religious sentiment which dominates it, impresses something solemn and sacred, even sacerdotal,” upon the practice of our art.<sup>1</sup> If we are to hold these heights we must make ourselves free of the best ideas of the age in which we live. Physical science, essential as it is, cannot alone give us that tincture of humanity—that breadth of sympathy, that knowledge of affairs—which is to be gained by conversation with philosophy and history, with ethics and politics: that is to say, with the thoughts, the hopes and the ends of mankind. We are not too much apart from the common polemics of the hour; indeed, I think doctors and clergymen are alike too ready to swim in these breakers. This notwithstanding, we are under temptation to carry all questions into our own province rather than to carry forth our own special knowledge to mingle with the broad current of the larger world. Hence we are too often provincial in our notions and in our ways of handling things, as all bodies of men become when shut up within their own gates. Our danger is greater as our studies by their special intricacy are more isolating and extend themselves by vast, continual multiplication. Moreover, our practice does not bring us widely into touch with the public; it is mainly domestic, personal, reclusive, and tends to catch rather the tone of the laboratory or the boudoir than of the world. The barrister, who in his practice is in daily contact with public affairs, has thus a great advantage over us in these things, and he passes readily from the Bar to the Cabinet. With a smaller academic education his view of life nevertheless widens, he gains more sagacity in the councils of the

State and is more in touch with the ideas of the day. He is shoppier enough, no doubt, really more shoppier by far than we are, but luckily for him his shop is of common interest; ours is technical, dry and often repellent. Thus it is that we find ourselves, and complain that we find ourselves, outside the sphere of government, ineffective in national debates and without that degree of consideration which we regard as our due. May there be grounds, indeed, for further warning, lest a devotion too exclusive to the schools of physical science—large and sinewy as the study is—should in the long run withdraw us too much from other studies more directly humane, from our attachment to traditional standards of ethics and politics, and from conversation in the sphere of idealised passion which we call things spiritual? Is not Nature, when at her best, ever weaving fresh brain webs, ever vibrating to finer and more complex external harmonies, which, as they continually become condensed, organised and rationalised, are nevertheless, as they grow on, as continually transcending reason? Do we not feel that some quality is lacking in the perfectly regulated and indifferent man, or in the man to whom age and failing fires have granted too much wisdom—that quality which the artist first reveals and which the man of science essays afterwards to interpret? Putting aside personal culture, have we not, in our relations to society, to minister not only to bodily ills in the grosser sense, but therein also to the defections of that exquisite sublimate of the body—the mind and imagination? If, therefore, our precious stores of knowledge and practical skill are to flow more freely and be seen more abundantly among men, we must enlarge ourselves by a broader culture than that of the medical schools. To our universities—present and to come—we commit this trust.

Another cause of our isolation lies in the exclusively technical course of our education, from which the “humanities” are more and more excluded. Thus we are removed from discussion with laymen and begin to regard our knowledge as too peculiar for common use. From this centre we have been rudely shaken of late years by the discipline of the witness box, where no oracular utterances are tolerated. The lawyer has taught the doctor at least one wholesome lesson—namely, that whoso cannot clearly explain his own propositions to an intelligent hearer does not thoroughly understand the matter himself. Our patients also have discovered this, and pretend that no gravity of countenance and no airs of profundity will satisfy those who come to us, not for discipline, but for information and advice. The information they will carry away if they comprehend it; the advice they will listen to if it be reasonable. We sometimes forget, however, that judgment and decision remain not with us, but with them. Our great but silent profession will find in time a larger voice and the honour of men. Nevertheless I do not burn for this fruition. Earnestly as I desire to see our culture broader and more humane, it is not for the gain of temporal power or splendour, but for the fuller interpretation of the higher life of our citizens. More than once I have publicly said, and I now repeat, that titles and the honours of the market place are rather for others; our calling, as Dr. Daremberg says, “has something religious, something solemn and sacred,” which ill accords with controversy and domination.

Within the compass of our thoughts this evening there lies a subject which during the last few weeks has been so publicly discussed that to keep silent upon it might seem in me like deliberate evasion. The public discussion of physiological experiment upon animals was, however, so heated that the moment seems unfavourable for a calm judgment on the matter. No compassionate person can fail to have considered well whether, as things are, experiments upon living animals be cruel or tend to diminish what I have called the general fund of pity. We can none of us regret that the question has been raised—a compassionate people is bound to look closely at such problems; nor can we regret that the practice is fenced by such reasonable checks as may prevent abuse. Whether the present checks are reasonable and sufficiently elastic is not a matter of principle, and may now be passed over. We are born into a world which, in its travail, wades through pain, torture and death as it rises in distressful victory from plane to plane of life. It is impossible by any mediation of man to alter this scheme—these essential conditions,—but it is the duty of man to mitigate and to economise the effects of this dispensation and to inquire of himself continually whether by all means he is diminishing the sum of hurt and distress in living things. This test must be final, and no other ultimate

<sup>1</sup> Vide Daremberg: *(Œuvres Choiesies d'Hippocrate, pp. 2 and 3. Paris, 1856.*

test of our means can be admitted or even conceived. Ends, certain saws notwithstanding, are the only tests of the means. Abraham and Agamemnon tried alike, acted alike, and if in matter of fact erroneously, yet in matter of ethics rightly. To extend or maintain our own particular dominion almost daily we send out, not animals only, but men also, and these in droves, to mutilation and death, staying mostly at home ourselves; and we are right. Your soldiers are said to like it—so do cocks; the question is of the greatness of the end. A Right Reverend Bishop tells us that the quantities of animals which he has slaughtered and devoured are sacrificed for the quality of his voice, and who is to say that the end does not justify the means? Not we who enslave or slay many more for profit, recreation or caprice, and win honour for it. The reduction of the sum of suffering in living creatures is, however, a far higher end than any of these; and we have to inquire whether experiment upon living animals is a means to this end, and if so, whether it be applicable. The answer is that it is applicable, and is applied daily and hourly almost everywhere. All practice of medicine and surgery, whether upon men or animals, is to experiment on them. In the older and simpler ways of practice we have experimented long and often, and made pretty sure; but these carry us over little ground, and an infinite gradation of certainty lies between the administration of such a familiar, but by no means guileless, drug as iodide of potassium, and such an intrepid and magnanimous experiment as that of Dr. Hankin, who, after prolonged testing of antidotes by himself and others upon animals, swallowed the virus of cholera intensified twentyfold, thus showing his faith in the relative value of results gained upon lower animals, and his ardent and generous search after an antidote to this devastating pestilence. I have taken two extremes, and I repeat that in and between these extremes all practice of medicine—even the very withholding of an ordinary drug—is experiment, and often very dark experiment, upon living beings, mankind or other kind, and that all change of remedial means and procedures consists in experiments ever renewed. Experiments upon living beings, for the good of living beings high or low, must therefore have been continual, and they must still continue if medicine is to advance beyond incantation and the horn of the unicorn. But, it is keenly urged, experiments upon animals in the laboratory are and have hitherto been sterile. This appears to me to be a vain, if not a stupid, argument. Such may or may not be the case. Our discussion is not of the present value of results, which may be useless to-day and precious to-morrow, but of a method which may have periods of hidden germination and periods of fruitfulness. In so highly technical a discussion few persons can take a useful part. Physiologists, however, do not work in mere frowardness, or only to attain that habit of accuracy which leads to truth; it is admitted that invaluable results have been reached by scientific investigations in other fields which at first sight seemed idle, which for long seasons were profitless, and which were carried out in a spirit of disinterested love of truth; and physiology is a science of like nature to other positive sciences. “Nothing, madam,” Sir William Gull once said on this subject—“nothing is so mischievous as ignorance.” The vanity of the argument, however, lies in this that it misses the whole point of principle. The question of principle must be thus formulated: granting that experiment upon living animals has led or may hereafter lead to gains infinitely valuable in respect of the cure or prevention of disease, am I in pity bound to forbid these experiments under all circumstances? I may lay down my own life, but am I to fortify my heart and watch my fellow creatures die of cancers, consumptions, malignant fevers and the like, and deny them admitted methods of help? In such case do I not consent to their fate, and, if so, can I justify so awful an abstention? This is the question of principle; it is applicable to the sufferings and death of all animals, greater and meaner; beside this question the accidents of more or less temporary success in discovery are subordinate, and may be considered by themselves in a competent court. But how is the question of principle to be answered? We answer it in one way; is there any competent and serious person who can deliberately answer it in the other?

Many more subjects akin to those which I have touched arise in my memory, and have doubtless arisen in yours, which might well have been discussed before you in this address. Already, however, I have bestowed too much of my tediousness upon you; the hour and your patience bid me conclude. Permit me to hope, encouraged as I am by

your kind attention, that the reflections which I have made to-night upon a few subjects may prove sound enough and broad enough to be applied likewise to others. Many of my hearers may have held before me the opinions I have uttered, to a few more I may perchance have carried conviction, and I am grateful to err in such company. Those who differ from me may, I trust, have found some materials for fresh thought and no matter of offence in the words I have ventured to speak on the opening of this session of the York Medical Society. To that Society I offer a present adieu and an abiding store of goodwill.

## THE ETHICS OF OPIUM AND ALCOHOL.

THE ANTI-OPIUM CIRCULAR TO THE MEDICAL PROFESSION OF GREAT BRITAIN AND IRELAND.

By F. J. MOUAT, M.D. EDIN., F.R.C.S. ENG.,  
LATE LOCAL GOVERNMENT INSPECTOR.

(Concluded from page 1093.)

I HAVE purposely in the preceding remarks excluded all reference to China for the reasons mentioned in my introductory observations, and because, in whatever light the commercial relations of India with China may be regarded, they have nothing to do directly with the treatment of its own subjects by the Government of India. It would still have to supply them with opium should the China trade be closed to them, of which the advent is not yet, although some intelligent Chinamen believe it to be approaching, from the action of the Chinese themselves. There is still one point connected with the Circular with which I have been dealing that I have not noticed—viz., that the free sale of opium in India tends to *immense acts of suicide*. The opium agent to whom I have more than once referred informed me that he never in any part of the country in which he has served heard of a single case of such self-sacrifice, and disbelieves in their existence. In my official tours of inspection, in which I visited every part of the Lower Provinces more than once, and had exceptional opportunities of acquiring information on matters connected with crime, I never heard of a single case. In Calcutta, with its population at the time I resided in it of more than half a million, I do not remember an inquest upon a case of the suicide of an opium-eater, and as most of these inquests were then held within the precincts of the Medical College, I should certainly have known of them, for when I was appointed Professor of Medical Jurisprudence I was kept informed by my friend the coroner, the late Mr. Piddington, of all crimes which came under his purview, for the illustration of that portion of my medico-legal lectures.

The latest information I have on the subject is in a recent work on Medical Jurisprudence in India, in which the number of fatal cases of poisoning by opium in five consecutive years—1885 to 1889 inclusive—is contained. They were—

In the Presidency of Madras ... ..	25 cases.
“ “ Bombay ... ..	81 “
“ “ Bengal ... ..	266 “

The Bengal cases apply to a population of nearly seventy-five millions of people, including 978,000 in Calcutta. If they were all suicides among opium consumers, which is most unlikely, such a drop in the ocean of humanity cannot be accepted as representing the “innumerable acts of suicides from opium” alleged in the Anti-opium Circular. A more convincing proof of the “falseness of extremes” it would be difficult to find anywhere.

The present Professor of Medical Jurisprudence in Calcutta, who is also police surgeon, in a publication of his medico-legal experience in that city between the years 1888 and 1890, mentions only one case of supposed poisoning by opium, and that a case of murder.

In the well-known work of Taylor on Poisons it is stated that in five years, 1863–7, there were 2097 deaths from poisoning in England and Wales, in 1270 of which the poisons causing death were ascertained; of these, 597 were from opium and its compounds. Such figures have never been attained among the millions of India, so far as I know. That many undiscovered cases may occur in that country is most probable; for even at home, in three-fifths of the deaths which

are ascertained to have been due to poisoning, the exact nature of the toxic agent is not discovered. But, as all the above statements can be verified, they dispose effectually of the myth of the innumerable suicidal deaths from opium in India.

Before considering the formulary of the Circular I must refer to the statement of Sir Charles Aitchison that "the question is not one of better or worse morality, but of the salvation of a whole people from a vice which we have introduced among them, and from a ruin which it is to a great extent in our power to retard, if not to prevent." With every respect for the opinion on State affairs of so distinguished a man as Sir Charles Aitchison, I am unable to accept either his premiss or his conclusions. A reference to the record of the mission of Mr. John Crawford to Burmah shows that a mission from China, which he met, after a conference smoked long pipes, which doubtless were opium pipes, as I am not aware that the Chinese smoked tobacco at that time, or at any time, in long pipes. The evidence of Mr. John Laird, a merchant who was imprisoned by the Burmese, stated that a considerable portion of the capital was occupied by a Chinese colony, some 3200 in number, and that among the articles imported by sea into Burmah was a "little opium." There was then and long before that time (1795) considerable intercourse between Burmah and China, and where Chinamen were, there was opium to be found. Sir Henry Yule, in his magnificent record of the mission to Ava in 1855, speaking of the import trade from China to Burmah, mentions spirits from rice for the consumption of the Chinese residents, tea, velvet, felt rugs, walnuts, chestnuts and *opium*, so he was assured. He adds, in a footnote, "Burney also mentions opium. It was sold in his time at one-fourth the price of Bengal opium, and was of very inferior quality. It was grown clandestinely at Talafec." How, then, we could have introduced a vice for the indulgence in which the material existed in the country long before we incurred any responsibility in the matter, and which was not a national habit of our own, I fail to understand. Surely it is far more reasonable to suppose that the credit or discredit is due to the Chinese, who do practise the habit, and carry it with them wherever they go. The use of opium in moderation is, I maintain, eminently and primarily a strictly moral and economic question, altogether irrespective of the collateral conditions attached to it. Whether the Burmese are more susceptible to the evil influences of smoking or eating opium than the Chinese or other nations, I know not. There are great differences in individuals in all such matters, and there may be exceptional differences in nations. I hope, therefore, that some light will be thrown upon this point by the inquiry which has recently been held in Burmah. But I am quite unable to accept the view of Sir Charles Aitchison on the matter. I have been a student of history all my life, and I have never read of any nation that has been ruined by its smaller curable vices. It happens that in the case of Aracan, inhabited by a race of strictly Burmese origin, which came into our possession at the same time as Assam, we have a living test of the question, which may be studied with advantage. I am informed by the officer most competent to express an authoritative opinion on the question, inasmuch as that province was under his able rule for some years, that the operation of the Bengal Abkaree regulations was extended to it immediately after its cession by the treaty of Yandabu. The result was, he said, decidedly beneficial, morally and physically, as I myself witnessed when I visited that province officially many years afterwards. It is singular that the smuggling of opium into Aracan from Upper Burmah also, long before its recent annexation, was extensively carried on. Most ingenious stratagems were resorted to for its concealment, and the opium smuggler was a well-known character. Where was this opium manufactured? It could not have been in India, where it was much too expensive to bear such transplantation. In 1851, on my return from Mauritius in a vessel carrying homeward-bound coolies, I fell in with a leading Chinese merchant of Calcutta, an old friend of mine. I asked him what took him to the island in the Indian Ocean, and he said to smuggle opium, of which he had succeeded in landing a fair venture. He told me confidentially how he had deceived the Customs authorities, and it exhibited considerable audacity and skill. He evidently considered us to be fools in the war of wits, and I do not think he was far wrong.

*Conclusions.*—Prior to examining the four specific questions submitted for the opinion of the medical profession at home, without in any way questioning the *bona fides* of the numerous signatories, I think I am justified in doubting and

denying the value of their assent, as I believe that the matter has not been fairly put before them. It is the work of a self-appointed tribunal whose means of personal acquaintance with most of the conditions alleged by them to exist were necessarily limited, and who have not supported their chief contentions by a single proof, as I do not hold bold asseverations to be entitled to be regarded as matters of fact, in the absence of even the shadow of evidence that is required to substantiate them. I do not regard the implicit adoption of the views of the Circular by sponsors from China as entitled to be considered at all in relation to questions of fact respecting a country and a people with which and with whom they are presumably personally unacquainted.

The *first proposition* is that "the habit of opium smoking and of opium eating are morally and physically debasing." This academic proposition is true only of the habits if carried to excess, and is indefensibly untrue of the moderate use of the drug, as the evidence which I have adduced appears to me to establish beyond the reach of doubt or denial by any reasonable or reasoning person. The opium broken-down drunkard is nearly unknown in India, so rare is his appearance. The moderate consumer is known to exist in thousands, possibly in much larger numbers, and amongst these are some of the finest races in India, mentally, morally and physically, as I know of my own personal knowledge, and as is more widely and generally known by the recorded evidence of thoroughly trustworthy authorities. It is idle to consider questions of such great importance in their scientific, social and political relations if the proofs of the facts necessary to enable a correct judgment of them to be formed are not given. Montaigne in his "Essay on Moderation" begins by saying that "if our touch is infected, we corrupt by our treatment things which are in themselves good and beautiful." So long as human nature is what it is, and the laws which regulate human actions are what they are, false, because misplaced, philanthropy, which is too often mere hypocrisy, causes damage, and destroys what it would be wiser to preserve and utilise under such restraints as can prevent their abuse. In the Circular it is paraded on Government authority that there are in British India 10,417 shops licensed for the sale of opium, and the incorrect inference is drawn that the Government by its excise regulations is forcing it upon the people by restrictions on the smallness instead of the largeness of its sale. It must be remembered that the above number of licences are for the supply of 287,223,431, or nearly 288,000,000 of people of many nationalities. Are the writers of the statement aware that the number of licences for the sale of intoxicating liquors at home in 1891 was as follows?—

Annual licences, England and Wales	...	184,743
" " Scotland	...	18,460
Licences to dealers or retailers of excisable liquors in Ireland	...	24,394

Do they venture to charge the British Government with any deliberate intention of degrading and debasing our population by forcing on them the enormous amount of agents far more destructive than opium, which are shown to be consumed at home? Instead of being astonished at the extravagance I am surprised at the moderation of the rulers of India in this matter. Of opium itself I could adduce an abundance of additional evidence of its comparative innocence as an intoxicant when compared with alcohol. The celebrated physician Sydenham regarded it as the greatest boon conferred by Providence upon humanity among agencies of relief, from the extent and variety of conditions in which it was useful and in which no other drug could replace it. The views of one of the most distinguished surgeons we have ever possessed—Sir Benjamin Brodie—I have already given. It would be easy to add to this list were it necessary.

The *second proposition* is that "the unrestricted sale of opium is immediately associated with many and grave dangers to the well-being of the people of India." My answer is that the sale of opium is, and has been for the last seventy years or more, very carefully restricted by the Abkaree regulations, and during this long period no public danger of any kind, grave or otherwise, has resulted that I either know or have heard of. This is another of those statements of which no proof has been afforded, for the population continues to increase with rapid strides, the prosperity of the country has increased in proportion, there is no general falling off in the morale and physique of the inhabitants of any part of India that I am personally acquainted with, and I have not found a single officer of experience acquired in other parts of our magnificent

empire who has seen anything of such a decline and fall. Even the opium dens of Calcutta, from a recent personal examination, appear to be models of propriety worthy of imitation by the gin palaces of this country, for I suppose no one has ever found one of these latter "as quiet and orderly as a prayer-meeting," such as Surgeon-Lieutenant-Colonel Crombie saw in Teretta bazaar, and which was also witnessed at the same time by a deputy-commissioner of police and by a European inspector. I passed that bazaar almost daily for thirteen years at all hours, and never saw an opium spectre emerge from it. I must therefore, until better informed, class this portentous prognosis of present and future perils among the fictions which abound in this Circular.

The *third proposition* is that "the drug opium ought in India, as it is in England, to be classed as a poison and be procurable from chemists only." Unfortunately for this recommendation opium in moderation is not a poison, and in its fiscal relations has much less business to be classed as a noxious agent than alcohol. It is treated, and rightly treated as respects its general use, in the same manner as alcoholic stimulants, by excise regulations and licences, which are far more stringent in India than at home. The proposition, then, is on all fours with a law, should any administration be idiotic enough to entertain or to pass it, that would require every glass of gin and whisky now obtained in a public-house, club, hotel or other licensed or unlicensed place at home, to be prescribed by a competent medical authority and purchasable only at a chemist's. But, still more unfortunately for this astounding want of acquaintance with the social condition of India, there is no class of chemists in existence in that country. I have visited every part of Lower Bengal, Assam and Aracan, and never heard of them among a population of some seventy millions of souls. When I was chemical examiner to the Government the wallet of every suspected professional poisoner arrested was sent to me for examination; and whilst I found in them datura, aconite and other vegetable poisons, as well as preparations of arsenic and corrosive sublimate, I never discovered a grain of opium that I can remember, as it is neither used as nor considered to be a poison by this class of natives. Has classing it as a poison in England and subjecting it to stringent conditions prevented its widespread use in the fen districts? Of it Dr. Ringer of University College says: "In this country the habit of opium eating is not so largely indulged in as among Asiatics, but it is practised here in some localities to a startling extent." In one of the classic reports of Sir John Simon is contained as serious an indictment against the abuse of opium in England as could ever have been written of its use and abuse in India. What chance, then, would dealing with it in the manner gravely proposed in this third count of the indictment, and applicable to millions of many nationalities widely differing from each other, have of success, were it even as practicable as it is impossible?

The *fourth proposition* is a corollary of its immediate predecessor, and is to the effect that "the Government of India should prohibit the growth of the poppy and sale of opium, except as required for medical purposes." This visionary suggestion might possibly be carried into effect in British India, but, were it so, would in that case at once stimulate an openly increased production in the native States not under our immediate control, and a surreptitious augmentation in our own territories. No agency that the Government could employ, at fabulous cost, could prevent such opium finding its way to those who were resolved to have it. Who would be able to determine its medical purposes, and what authority could exercise any control over its sale in that sense, by the (non-existent) chemists, who would have themselves to be created? Leaving China and the Chinese in their own country out of the discussion, which relates only to India, what example have we of any civilised people among whom the opium habit exists largely, as to the effects of its practically unrestricted use, on the moral and physical condition of the people? In 1880 the opium smokers in the United States of America were estimated at nearly a million, and they are probably more numerous now, as the habit was then said to be increasing. Has any general moral or physical degeneration among this great body been observed and recorded, such as to constitute a national calamity or disgrace? I have no means at the present moment of ascertaining the views of the medical profession in the great republic on the subject, but I observed no such effects when I visited America in 1861, and I heard nothing of it from any of the American professional men with whom I came in contact.

Of the Chinese out of China; I have come into contact with two communities—one in Calcutta, small; the other in Singapore, very large; and among neither of them did I hear of, or see, any examples of those presented in such dark colours by the anti-opium agitators. With those in Calcutta I had, as already said, an intimate acquaintance, and there was not one that I saw or heard of to whom the reproach of being an opium drunkard could be attached. They were a healthy, vigorous, quickwitted and excellent body of men, with no indication of moral or physical degeneracy. I visited Singapore nearly thirty years ago, when the Chinese colony was computed at 40,000, of whom 15,000 were known to be opium consumers. Both numbers, I have been recently told by an officer who dwelt long among them, have increased considerably since. With my friend, the late Sir Orfour Cavenagh, at that time Governor of the Straits Settlements, I visited the Chinese quarter, and from him I obtained much information regarding them, and saw and heard nothing to indicate anything in the least approaching to general moral, mental or physical degradation. Similar testimony respecting this community was given by Sir Frederic Halliday before the Committee of the House of Commons already referred to. According to the census just taken, Rangoon, with a population of 180,000, has a Chinese contingent of 8029, of whom 6155 are males. A gentleman who occupied for some time a leading position in the business portion of that community told me, within the last week, that he never met with a more intelligent, healthy and capable body of men than the Chinamen with whom he came in contact. Those who emigrate must then be either selected specimens of their race, or exercise more control over their actions and appetites than those they leave behind them. It is, I think, to be regretted that the anti-opiumists who paint the Chinaman in such dark colours in his own home have not, so far as I know, collected and published detailed statistics of the numbers, ages, occupations and proportion to the rest of the communities of which they form parts, of the victims of the opium habit carried to excess, should such figures be procurable. If collected with the rigorous exactness required in all statistical inquiries, these figures would carry more conviction than any unsupported statements can or ever will do.

And now, having considered the assertions and propositions contained in the Anti-opium Circular, I am in a position to ask whether those who are clamouring for the suppression of the general use of opium in India, have considered the alternatives which would inevitably follow the complete disappearance of that drug as a general stimulant? These would, in my opinion, be gunjah (already largely in use) and alcohol, because these are and must remain the cheapest substitutes, and those most within the reach of the labouring classes. The former is too well known as a prolific source of crime and insanity, and the action and effects of the latter would be very much the same as they are in Europe, as I know from having had a few alcoholic native drunkards in my wards, when I was a hospital physician. Where would be the advantage of substituting more mischievous for less harmful stimulants under any plea whatever, for opium has not yet been shown in India to occupy the post of preëminence in moral and physical deterioration, that alcohol certainly fills amongst ourselves? I can only apply to the craze on the subject the dictum of Ilorace:—

"Inveni sapiens nomen ferat, æquus iniqui  
Ultra quam satis est virtutem si petat ipsam."

What is really wanted for the settlement of the question—if it ever can be settled—is a more exact collection of well-considered and supported facts, and less exaggeration in their interpretation. Regarding these conditions what said the bard whose loss we are all now deploring?—

"Her open eyes desire the truth;  
The wisdom of a thousand years  
Is in them. May perpetual truth  
Keep dry their light from our tears,  
That her fair form may stand and shine,  
Make bright our days and light our dreams,  
Turning to scorn with lips divine  
The falsehood of extremes."

Athenæum Club.

PRESENTATION.—Dr. Guillemard, lately ordered to South Africa on account of his health, has been presented with a testimonial consisting of a purse of £175, and a parchment scroll upon which is engrossed an inscription testifying to the sincere regret of his friends and patients on the occasion of his leaving Southsea.

## INTUSSUSCEPTION AND ITS TREATMENT BY OPERATION: ILLUSTRATED BY TWO CASES.<sup>1</sup>

By FRANCIS J. SHEPHERD, M.D., C.M.,

PROFESSOR OF ANATOMY AND LECTURER ON OPERATIVE SURGERY,  
M'GILL UNIVERSITY, MONTREAL; SURGEON TO THE MONTREAL  
GENERAL HOSPITAL.

THE treatment of this somewhat rare affection has always exercised the minds of practitioners, but of late years, owing to the enormous strides made in aseptic surgery, abdominal section has become a recognised form of treatment, and hence intussusception is now looked upon by advanced men as a purely surgical condition, quite as much so as strangulated hernia. The results of abdominal section so far have not been brilliant, owing chiefly to the delay with which the operation is undertaken; the conditions resulting from the prolonged invagination being such as to necessitate so formidable a procedure as resection of the bowel, an operation attended with much mortality, even when performed in non-gangrenous cases. Mr. Arthur Barker in 1888 collected 73 cases of intussusception which had been treated by abdominal section; 13 only of these cases recovered; in 34 the bowel was simply released and no further operative measures undertaken, yet only 12 recovered. In 133 cases recorded by Mr. F. Treves there was a mortality of 72 per cent.; when reduction was easy, in 30 per cent., and when difficult, in 91 per cent. The reasons for this great mortality are (1) the tender age of the patient and (2) the late performance of the operation. Operations on infants, in whom the affection is most commonly seen, are rarely successful, the patient usually dying of shock caused by the necessarily prolonged manipulation of the bowel which is needed to reduce the invagination. Now, what should first be done when we are confronted with a case of intussusception? Should other means than operation be first employed? Certainly, it would be well first to arrest the peristaltic action of the bowels by the administration of opium or even to give emetics. We should then try to force back the invaginated bowel (which can nearly always be felt through the anus) by means of air, hydrogen gas, or water injected per rectum, whilst the patient is under the influence of an anæsthetic. Probably air or gas is safer than water, being lighter and less liable to cause injury to the bowel. This method has been fairly successful, especially in children under one year. Should it fail, then immediate resort should be had to abdominal section. This should be in the median line, and when the tumour is come down upon, by careful manipulation we should try to pull out the invaginated bowel, not using too much force. Even if there be no adhesions great difficulty is often experienced in reducing the intussusception, owing chiefly to the resistance offered by the ileo-cæcal valve and the cæcum. This is seen in one of the cases narrated below. When the invagination has been reduced the bowel should be carefully examined for gangrenous spots and rents. The gangrenous areas should be excised and the rents sewed up. If we find the bowel gangrenous throughout, resection is our only resource. Resection is rarely successful owing to its tediousness and the shock caused by the operation on an already enfeebled individual. Senn advises lateral anastomosis in cases where the bowel is not gangrenous but cannot be reduced, or where the continuity of the bowel cannot be restored by circular suturing because of the difference in size of the two ends of the resected bowel, or owing to inflammatory softening. The plan adopted by myself in Case 2 seems to me to be preferable to lateral anastomosis in cases of irreducible and non-gangrenous intestine. Should the bowel, however, prove gangrenous Barker's operation may be proceeded with through the same incision. Some recommend that an artificial anus be established. The results of this procedure have been, however, almost uniformly unsuccessful. Mr. Arthur Barker<sup>2</sup> recommends an ingenious procedure, the feasibility of which is very attractive, and I have been waiting ever since reading his paper for a suitable case in which to put this method into practice. It is briefly as follows: "At the point at which the intussusciptens receives the intussusceptum the two portions of the bowel are at once

united by continuous circular sutures of fine silk, taking up the serous and muscular coats of each and carrying the sutures on to the mesentery. A longitudinal incision is then made for about two inches through all the coats of the intussusciptens in its free margin. This gives access to the sausage-like intussusceptum. The latter is then drawn through this incision and cut across at its upper end, or if too long to be drawn out is first cut across *in situ*. A few stout ligatures are, however, passed through all the walls of the stump as the mass is gradually cut off, and are tied tightly so as to keep the serous surfaces in contact and control all bleeding vessels. The stump is now cleansed, dried and dusted over with iodoform and allowed to drop back through the incision into the intussusciptens, and the longitudinal incision in the latter is closed by a continuous suture from end to end." Mr. Barker has operated in two cases, but both ended fatally, owing to the fact that the operation was undertaken too late. It appears to me that this operation has much to recommend it, being more rapid and safer than resection, and infinitely to be preferred to the formation of an artificial anus.

In the cases narrated below the conditions were not such as were suitable to the performance of Barker's operation, but I hope at some future time to test its efficacy. In my two cases one was successful, but the other, owing to the tender age of the patient and the prolonged manipulation necessary to reduce so large an invagination, succumbed.

CASE 1. *Intussusception in a child aged six; abdominal section; recovery.*—E. A.—, aged six, was seen by Dr. Finley on the afternoon of Feb. 13th, 1892. She complained of severe abdominal pain, which commenced about 8 A.M. and was attributed by the mother to over indulgence at a Sunday school feast attended the night before. The child had vomited several times during the day; next day a considerable amount of blood and mucus was passed per rectum. On Feb. 15th pain and vomiting continued; pulse rapid and small; temperature normal; tongue thickly coated. Now for the first time Dr. Finley discovered a small indistinct tumour below the ribs in the left side and outside the linea semilunaris. Recognising the case as one of intussusception and remedies proving of no avail I was called in to decide as to the expediency of operating. At 5 P.M. on Feb. 15th the child was put under ether, and a rectal examination immediately revealed a sausage-shaped tumour. No tumour could at this time be felt in the abdomen above. The tumour could be pushed back, but it almost immediately returned. Water was forced into the rectum in large quantities, and for a time the tumour disappeared from the rectum, but reappeared in the abdomen, and after a few minutes was again seen presenting at the anus. This procedure was repeated several times, when, not wishing to lose any more time, I advised removal to hospital and immediate abdominal section. This was done, the operation being performed about 8.30 P.M. The tumour could still be easily felt through the rectum, though it did not now pass the anus. The child having been placed under chloroform, a median incision was made below the umbilicus and the abdominal cavity opened; the finger was introduced and a tumour felt, which on slight traction of the bowel immediately disappeared. The abdomen was now most carefully examined to find if any other tumour existed, as I could hardly believe that the invagination could have been relieved with so little manipulation. On examining the bowels the descending colon was found to be deeply congested at one point, and near this a scybalous mass was felt in the bowel; it seemed like a foreign body, but could be easily moved on. The wound was closed with a few silk-worm-gut sutures and dressed with absorbent cotton. The child did perfectly well and had a natural stool within twenty-four hours. In ten days she was discharged from the hospital and has been in good health ever since. In this case the tumour was distinctly felt through the rectum before the abdominal incision was made, and immediately before entering the hospital the child had passed considerable quantities of bloody mucus, and had experienced much pain and vomited, yet the opening of the abdomen followed by the slightest manipulation of the intestine, was sufficient to reduce the invagination. It may be that the intussusception had already begun to be relieved before operation was undertaken and that the operation merely hastened the process. Still the fact remains that after several attempts at reduction by forcing water up the rectum the tumour still could be felt and seen at the anus, and that it did not disappear until the abdomen was opened.

CASE 2. *Intussusception in an infant aged seven months; operation; death.*—B. D.—, a strong healthy infant, aged

<sup>1</sup> A paper read before the Canadian Medical Association at Ottawa, Canada, Sept. 14th, 1892.

<sup>2</sup> THE LANCET, Jan. 6th, 1892.

seven months, began to suffer from severe pain, accompanied by vomiting and the discharge of bloody mucus per rectum, on May 6th, 1892. Dr. Elder was called in on Sunday, May 8th, and immediately recognised the case as one of intussusception, a dark-coloured tumour presenting at the anus. I was consulted about the case and advised immediate removal to hospital. At 6 P.M. on May 8th I first saw the patient. At that time she was suffering considerable pain and had extreme distension of the abdomen. Protruding from the anus was a dark-red sausage-shaped tumour, which, on examination, proved to be an intussusception. Abdominal section was immediately decided upon, as the employment of other methods of relief was thought to be useless owing to the condition of the patient and the length of time the affection had lasted. The child was placed under chloroform, and an incision three inches long was made in the median line, commencing at the umbilicus. On opening the peritoneal cavity the distended intestines immediately protruded. So great was the distension that it was useless to try to reach the seat of the intussusception without allowing the intestines to protrude. The greatly distended small intestines which extruded themselves were covered with hot towels. Now the tumour was easily found, and it filled the true pelvis. The tumour, on examination, proved to be a greatly distended rectum, into the upper end of which some small intestine was seen to pass. With the exception of the rectum, no large bowel was to be seen. I tried to release the bowel by moderate tension, which was gradually increased, but without effect, although there were no evidences of inflammatory adhesions present. Feeling that it would be useless to employ any more force, the large bowel (rectum) was incised longitudinally and the intussusceptum exposed. The incision gave exit to a large quantity of dark grumous bloody fluid. Efforts at reduction from within were now made, and, aided by an assistant's finger in the rectum, I managed to release some of the bowel. First came a portion of the lower end of the ileum; the cæcum and appendix came next like a cork out of a bottle, and the rest of the large intestines slowly unfolded themselves. A lump still remained, however, and it was found to be another intussusception, which was invaginated from below upwards. This was easily relieved, and all parts of the bowel were free. Many portions were much congested, but there were no evidences of inflammatory adhesions. The incision in the rectum was now rapidly closed with a continuous Lembert's suture of fine silk and the abdominal wound sewed with silkworm gut, a glass drainage-tube being inserted at its lower end. The patient suffered much from shock after the operation and only lived some three hours. In this case the large amount of the invaginated bowel, the great distension and the amount of manipulation necessary to relieve the invagination, taken together with the tender age of the patient, were quite sufficient to cause death. Although there were no inflammatory adhesions, still the difficulties of reduction were great and invagination could not have been relieved without incising the bowel. The obstruction to reduction was manifestly the bowel about the ileo-cæcal region. It seems to me that incision of the bowel and relief of the tension, with pushing of the invaginated bowel upwards, are better methods of treatment in non-gangrenous cases than either tubal anastomosis or the establishment of an artificial anus. If the bowel should prove gangrenous, then Mr. Barker's operation could be easily proceeded with.

Montreal, Canada.

## THYMOL AS AN ANTHELMINTIC REMEDY.

By PROSPERO SONSINO, M.D. PISA.

THE history of the greater number of new drugs proposed as remedies is generally as follows. A certain substance is suggested as a remedy against a particular disease. After some hesitation we find the new drug extolled by numerous observers in every quarter of the medical world—as yet, however, only as against one particular disease. After a time its use is generalised, as it were, and extended to other ailments, and we now find its virtues lauded in many cases and many diseases. By-and-bye a reaction sets in, drawbacks are discovered, it is no longer the general panacea, and it is only after a long time that the true therapeutical position of the

drug is at last defined, if it does not eventually fall into complete disuse and oblivion. It seems that thymol is now passing through the common ordeal: it was first used by Bozzolo<sup>1</sup> in 1880 against anchylostoma. After some hesitation its efficacy was confirmed by many practitioners, and it is now accepted as the best remedy in anchylostomiasis in such a manner that it has generally superseded the liquid extract of male fern, which was the only other remedy that for some time could compete with it; but the efficacy of thymol in anchylostomiasis was hardly well established when already it was tried in other ailments, and especially as a general anthelmintic remedy. At the present time, if we would trust the assertions of some hasty advocates, it is the best remedy against all the intestinal worms, tænia among the number, and also against lamatozoa, as *filaria sanguinis hominis nocturna*. I think great credit is due to Dr. Crombie<sup>2</sup> of Calcutta for having shown that about ten grammes per diem of thymol, given for three successive days, are not enough to cause the disappearance of the embryo *filaria* from the blood, contrary to what has been asserted by others who state that daily doses of some fraction of a gramme of this drug, taken for a certain number of days, are sufficient to cure radically filarial disease. We have seen more recently the inefficiency of thymol against *filariæ sanguinis hominis* confirmed by Dr. Manson.<sup>3</sup> Perhaps Dr. Crombie has been too hasty in believing that thymol, while impotent in the case of the *filariæ* of the blood, is nevertheless effective against intestinal worms, tæniæ included. I desire to bring forward in the columns of THE LANCET the result of my experience on this subject. Whilst I have had numerous brilliant successes with thymol in anchylostomiasis, so that in this disease I can testify that it acts often as a charm, I must confess that there are some cases, rare it is true, in which I really found difficulty in ridding the intestine of anchylostomes even with this remedy. I had recently in hospital a long-standing case of chronic disease, which was complicated with anchylostomiasis. The administration three times of a total daily dose of four grammes brought away in all thirty-one anchylostomes; but even after the third administration of the drug the stools contained anchylostoma eggs in as great abundance as previously to the commencement of the thymol treatment, and as they are found in the stools of patients from whom thymol expels some hundreds of anchylostomes, I could not explain in a reliable manner the cause of this non-success. I argued that it might be due to the circumstance of there being a certain number of worms hidden in the walls of the intestines and others under the folds of the valvulæ conniventes in such a manner that the thymol may have passed without exercising its toxic action upon the parasites, or it might have been that an extraordinary abundance of tenacious mucus enveloped the worms, and so preserved them from the action of the remedy. Unfortunately the patient, who one year before had been operated on for an abscess of the liver, and who had fallen into a state of marasmus from diarrhoea and vomiting, became worse, and, seeing his end approaching, preferred, in September last, to leave the hospital and go home to die. Consequently no post-mortem examination could be obtained whereby the number of anchylostomes could have been counted, and the reason for their non-expulsion by the thymol explained. Such rare cases as this of non-success must not detract from the merits of thymol as a remedy against anchylostomiasis. I wish, however, to insist that its efficiency in anchylostomiasis cannot in any way authorise us to proclaim it a universal anthelmintic, applicable to all intestinal worms, without positive proofs of its efficiency in the case of each individual species of parasite. I can assert that the only worms I have occasionally seen expelled along with the anchylostoma after the administration of thymol were *ascaris lumbricoides*, *oxyuris vermicularis*, and *trichocephalus dispar*. But whilst the expulsion of anchylostoma is the rule with thymol, this drug acts on the other worms mentioned only exceptionally, in the majority of instances failing entirely to cause their expulsion. Consequently in *ascaris lumbricoides* I cannot trust to thymol so much as I can to other ordinary remedies, such as santonin, for which I now prefer, on account of its insolubility, to substitute its product *santoniossima*, introduced by Coppola. As for *oxyuris vermicularis*, which, on account of the liability in the case of this parasite to self-

<sup>2</sup> THE LANCET, Aug. 13th, 1892.

<sup>3</sup> THE LANCET, Oct. 7th, 1892.

infection, is of all the intestinal worms perhaps one of the most difficult to completely eradicate, I have not found that with thymol we can get rid of it more completely than we can with the other means at our disposal, especially when they are applied by enema. Respecting trichocephali the difficulty in procuring their expulsion with any remedy is well known. After my first trials, in which I found in some cases trichocephali in the stools following the administration of thymol, I entertained the hope that this drug might prove an efficacious remedy against this worm. As the ordinary seat of the worm is the cæcum, I suggested that its expulsion might be better assured by using thymol in enema. But if used in this way, as the thymol must be given in solution, I now fear that it could not be administered in doses sufficiently large to prove efficacious without proving hurtful to the organism of the host from absorption. Indeed, thymol introduced into the circulation is certainly a poison, even in small doses. If we risk giving it in such large doses as four, six, eight, and even ten grammes per diem, it is only because we administer it in powder, and can trust that, if absorbed at all, it will only be so in a very minute amount. The evidence of absorption having taken place is afforded by the patient being attacked with vertigo, and by his urine becoming brownish. These unpleasant symptoms are only met with in rare cases after the administration of such a dose as four grammes of thymol. From what I have said I think it will be seen that thymol will not prove so sure a remedy against the three nematodes named as it is against anchylostoma. As for tænia, I have never tried thymol against tænia solium or tænia mediocanellata, because I think that pelletterine properly administered is now the best remedy against the large tapeworms. I can say, however, that in cases of anchylostomiasis complicated with tænia nana I obtained with thymol the expulsion of the former, but not of the latter. The tænia were expelled only after recourse was had to the liquid extract of male fern and calomel. In a case of tænia nana in a child two years of age I succeeded the other day in bringing away more than 1000 specimens of this small cestode with only one gramme and a half of liquid extract of male fern combined with fifteen centigrammes of calomel.

I have never read of any well-ascertained instances of expulsion of the large tapeworms by thymol, and I should be grateful to Dr. Crombie or to any other practitioner for publishing such cases, with full particulars, if they are acquainted with such cases. Indeed, it seems to me that the results of Bozzolo's and Lutz's experience, though contributing perhaps to the wider adoption of thymol as a general anthelmintic, especially against tænia, are not so conclusive as to replace pelletterine by thymol. Bozzolo, in the work cited, speaks only of a case in which after the use of thymol he did not succeed in seeing the scolex with the strobila. He adds that the patient (a woman) after eight months had not passed any proglottides, and that she felt well. Lutz,<sup>4</sup> in his last work, says he has never seen the complete expulsion of a cestode by thymol; nay, in two cases of bothriocephalus he has ascertained that after some time the patients still suffered from the presence of the worm. Only in some cases of tænia had he noticed that after incomplete expulsion the worm no longer appeared. After all, Lutz only declares that thymol had proved for some patients the more agreeable remedy, but at the same time he put it in the second line, and after pelletterine and koussine. Giles,<sup>5</sup> who more recently has had the opportunity of trying thymol on a large scale against the anchylostoma in Assam, says that he had no occasion to try it against tænia; but that from what he gathers from others thymol would appear to be a far more efficient vermifuge in dealing with tænia than male fern or any of the other drugs more commonly used for that purpose. But among the latter he does not mention pelletterine. Having nowadays at our disposal pelletterine, I think it useless to have recourse to thymol, which certainly offers more drawbacks than pelletterine. Dr. Walker,<sup>6</sup> in Sandakan Hospital (British North Borneo) and Giles, in Assam, each obtained once the expulsion of a specimen of distomum crassum by thymol used against anchylostoma. Certainly these two observations (up to the present there are no facts telling against them) are in favour of the efficiency of thymol against the large Asiatic fluke. But we cannot forget that in a case cited by Cobbold the expulsion of

several specimens of this fluke followed the employment of a milk diet simply; and in other cases the same result has followed a milk diet unaided by any other treatment.

To conclude, I think it would be a therapeutical mistake to infer that a substance which is truly efficient against some given parasite must also prove successful as a general anthelmintic. Experience teaches us the contrary in the case of every drug having an action on some particular worm. As for thymol, I can assert as the result of my experience that it is an effective agent generally against anchylostoma, but very uncertain against the other three intestinal nematodes I have referred to, and entirely ineffective against tænia nana. As for the method of administering thymol, I think that the best plan is to give it in powder in wafers or cachets. I find that tabloids are not of any advantage, because so many have to be taken at a time if we wish to introduce the drug in doses of several grammes, and that the thymol being acrid, the direct contact with the mouth might prove hurtful.

Pisa.

### ON THE METHOD OF ESMARCH AND BIER FOR THE CONSERVATIVE TREATMENT OF TUBERCULOUS JOINTS.

By HERBERT W. PAGE, M.A. CANTAB.,  
SURGEON TO ST. MARY'S HOSPITAL.

In September last I had the good fortune to make a visit to the hospital at Kiel in company with Professor Esmarch and his assistant, Dr. Bier, and was shown a series of cases illustrating a new method of treating local tuberculous affections which I wish to bring to the notice of English surgeons.

A short account of the plan from the pen of Dr. Bier had indeed already appeared in the supplement of No. 32 of the *Centralblatt für Chirurgie* of this year, which contains a report of the proceedings of the twenty-first Congress of German Surgeons held in June; but it escaped my notice, as doubtless it has escaped that of other surgeons in this country. The treatment advocated is, however, of so much interest and apparently of such value that I deem it right to record this notice of it now, even though I have myself had no sufficient opportunity of putting it into practice. The original paper of Dr. Bier is entitled "A New Method for the Conservative Treatment of Joint Tuberculosis," and in it he says that more than twenty cases had been treated by continuous passive hyperæmia (dauernder passiver Hyperämie). The old observation that passive congestion of the lungs (Stauungslunge) provided, or seemed to provide, immunity against tubercular infection had led to the suggestion that purposely induced congestion of a part might have a like effect. Accordingly the idea had been put into practice by the following simple procedure, much after the manner of Helferich, for the treatment of ununited fractures. If, for example, the part affected is an elbow-joint, the fingers, hand and arm are bandaged up to a point immediately below the articulation, while directly above it the arm is next encircled with an inch-wide elastic band sufficiently tight to impede but not arrest the circulation, and so presently induce a passive congestion and swelling of the intervening zone. It is necessary, he says, to protect the skin from direct pressure of the elastic band by a piece of lint or bandage beneath it, and the exact site of its application must be changed from day to day. In most of the cases where this plan had been carried out in Professor Esmarch's clinic marked and rapid improvement had set in, and in no instance had any harm ensued. Dr. Bier says that he had also induced active hyperæmia, but without good result. He does not state precisely how this was done.

This plan of treatment by passive congestion was that which I saw in the hospital at Kiel. To take a couple of instances which recur to my mind: there was a case of tuberculous synovitis of the elbow in a young woman. Under the method of bandaging described the whole joint area was of a reddish-purple, congested appearance. Painful and starting before the treatment had been begun, the joint was now free from pain, even though no attempt was being made to keep the part at rest. In fact, I was assured that splints were wholly unnecessary, and that the limb might be used as much as the circumstances of its imprisonment in bandages would allow. Although the method of treatment is somewhat painful for a day or two at first, the part is soon free from discomfort of

<sup>4</sup> Klinisches über Parasiten des Menschen &c.: *Centralblatt für Bakteriologie und Parasitenkunde*, 1888, Band iii.

<sup>5</sup> A report on Beri-beri. Shillong (Assam), 1890.

<sup>6</sup> Two cases of Beri-beri associated with *Distoma crassum* and *Anchylostomum duodenale* &c., by J. H. Walker, M.D.: *Brit. Med. Jour.*, Dec. 5th, 1891.

any kind; manipulation in this particular instance caused no pain, and the patient said the arm was very much better. Her complete recovery was expected. Not less striking was a case of tuberculous ulceration of skin due to inoculation. A young man had used milk to remove old tattoo marks. I did not learn the exact method he had adopted; but there seems to be a belief that milk can eradicate tattoo marks, by rubbing out the black with white. At any rate, in this patient the sites of the tattoos, three or four in number, immediately above the left wrist were now occupied by tuberculous lupoid ulcers, and I was informed that investigation had proved that the milk the man had used was taken from an infected cow. Suffice it to say that there were now sores of unquestionably tuberculous lupoid aspect, and one of them, of the size of a florin, had healed entirely under the method described and without any local application. This patient came to the hospital every morning to have his fingers and hand bandaged and the position of the encircling rubber band changed. Amongst other cases being treated in the same way were a tuberculous swelling of knee-joint and a tuberculous epididymitis, both of which I was assured were notably improving. The plan was said to be suitable for local tuberculous of the skin and for tuberculous affections of synovial membranes, but not for disease of cartilage or bone. For the treatment of many other cases it is obviously inapplicable.

I have thus described what I saw, and make no apology for a communication without experience of my own, feeling that anything new in the clinical work of a surgeon so illustrious as Professor Eschmarch of Kiel cannot fail to be of interest to many besides myself. This plan of treatment will at any rate give occasion for speculation and thought, and certainly for much scepticism also. When the treatment of tuberculous affections by the injection of Professor Koch's tuberculin was being tried, it was often remarked that in the local inflammatory reactions probably lay any good which followed. Mr. Hutchinson recurs to the subject in a short paper on the "Benefits accruing from Erysipelas," in the last number of his Archives,<sup>1</sup> where, after speaking of the benefits which accrue to lupus vulgaris from attacks of erysipelas as matters of frequent and general observation, he goes on to say: "The local effects of Koch's treatment, when good reaction was obtained, were not dissimilar from mild erysipelas, and it seems possible that their beneficial results may have been due simply to the febrile disturbance evoked." The plan of treatment here described, as seen at Kiel, brings about a local disturbance not altogether unlike the local disturbances induced by Professor Koch's inoculations—disturbances which seem to show that the quantitative and qualitative alterations in the blood and blood stream which we know by the name of inflammation may have an influence directly antagonistic to the growth and multiplication of micro-organisms. Comparatively harmless when circulating in the blood current, their opportunity comes when they have made their way out of it or are arrested in it, and the flushing of a part with blood in the inflammatory process may have its good effects not so much from flushing and washing alone as from the fact that living, fluid, healthy blood, is itself the best protective against the growth of living organisms foreign to their host. More blood is wanted for the purpose of protection than the natural rate and character of the circulation provide, and the artificial increase and delay of it in the neighbourhood where the organisms have made a lodgment by the method of Professor Eschmarch and Dr. Bier may bring just that amount of extra help which the tissues of the part require successfully to overcome the tubercle bacilli and put an end to the consequences which their presence entails.

My object, however, is not to speculate on the *rationale* of the plan, but to ask English surgeons to try it, that haply they may find in it, as at Kiel it is said has already been found, an effective means for dealing with local tuberculous disease.

<sup>1</sup> Vol. iv., No. 13, p. 70.

A MEETING of the British Medical Temperance Association was held on Tuesday at 20, Hanover-square, W., presided over by Dr. B. W. Richardson. Dr. Norman Kerr read a paper on some recent returns of the consumption of alcohol in workhouses. He stated that a decided decrease had taken place in the use of alcohol in workhouses as compared with former returns, and that the condition of the inmates as regards health, comfort and discipline had shown a corresponding improvement. He suggested that a leaflet should be prepared to instruct parents as to the injurious effects of supplying intoxicating drinks to children. Resolutions to the same effect were moved and carried.

## CHOLERA AND DISINFECTION IN ST. PETERSBURG.

By FRANK CLEWOW, M.D.

THE importance of thorough disinfection in the presence of cholera is so universally recognised that no apology is needed for the following notes on the methods advocated and employed in St. Petersburg during the present epidemic. In the large hospitals of this city, where as many as two or three hundred cholera patients have been under treatment at the same time in one institution alone, the question of disinfection has been one of the first importance, not diminished by the facts that all the liquid portion of the excreta passes directly into the drains, the drains open into the canals which intersect every part of the city, and the canals communicate directly with the river Neva. Various methods have been used for the disinfection of the dejecta, of wearing apparel, of bed linen, of the walls and floors of rooms or wards, of furniture, and finally of closets, dustbins and drains. In the following notes each of these objects is considered in the order named. The dejecta naturally claim the first place. The most usual method employed has been to add to them a solution of carbolic and sulphuric acids. This solution is prepared as follows: To three parts by weight of impure carbolic acid (50 per cent.) add one part of sulphuric acid; this must be done slowly, with sufficiently long intervals to prevent the development of heat, and with constant stirring. It is advisable to surround the vessel containing the mixture with ice or cold water. The mixture is allowed to stand for two or three days. When required for use it is diluted by adding 1½ lb. to 1¾ lb. (615 to 682 grammes) of the mixture to a vedro (21½ pints or 12·3 litres) of water, with energetic stirring. In this way is produced a from 5 to 6 per cent. sulpho-carbolic solution. The dejecta having been collected in wooden barrels, well tarred on the inner surface, an equal amount of the sulpho-carbolic solution is added and the mixture stirred. This has been found by experiments made by Dr. Levin at the Obuchovski Hospital to be efficient, attempts at cultivations from the dejecta thus treated having proved abortive. But as heat is considered the most absolutely certain method of sterilising fluids, the further process of boiling the dejecta has been adopted. The Alexander Hospital, founded in memory of Professor Botkin (the large city hospital for infectious diseases, devoted this summer entirely to cholera cases), enjoys the distinction of being probably the only hospital in existence possessing an apparatus for boiling all infectious dejecta. It is unnecessary to describe the apparatus fully here, as it is the intention of Dr. Richard Sisley to show drawings of it, with full explanations of its working, at an early meeting of the Society of Medical Officers of Health. It need only be stated that not only the dejecta, but also all fluids from the post-mortem room are in this apparatus submitted under pressure of a temperature exceeding 100° C. before being allowed to pass into the drains. Another means used for sterilising dejecta has been to add a 20 per cent. milk of lime, prepared as follows: To 20 parts by weight of lime, which should preferably be newly burnt, are added 80 parts of water in a wooden or earthenware vessel, slowly and with constant stirring. After this solution is added to the dejecta the mixture should be allowed to stand for three or four hours. A solution of chloride of lime may also be employed of a strength of from 2 to 4 per cent.

Wearing apparel is treated according to the material of which it is made. All linen garments (to which may be added sheets, towels &c.) are on removal from the patient rolled up in a sheet or put into a bag moistened with a 4 per cent. solution of chloride of lime and removed to the disinfectant. They are immediately placed in a hot solution of carbolic acid and soap and allowed to soak for one hour. This solution is prepared thus: Pure carbolic acid (100 per cent., if of less pure quality some of it remains undissolved, and may stain linen) is added to a solution of soap in water in the following proportions: To one vedro (21½ pints or 12·3 litres) of water, in which are dissolved 1½ lb. (615 grammes) of soap, are added 200 grammes of the acid. The solution should be clear and of a yellowish colour; it is used at a temperature of from 50° to 80° C.

<sup>1</sup> In the Russian Pharmacopœia one pound (fluid or solid) equals 12 oz. Throughout this paper the Russian pound alone is spoken of.

Woollen clothes, and indeed all articles that are not spoilt by moist heat, are disinfected by the action of steam at a temperature of 100° C. This question has received the most detailed consideration at the hands of Dr. Krupin, who is in charge of the large disinfecting camera at the above-mentioned Alexander Hospital. Here the chamber into which the steam is admitted is rectangular; at each end of the chamber is a door opening into separate rooms, the one for receiving infected articles, the other for removing them after disinfection. A thermometer is inserted in the centre of the articles with an automatic arrangement for ringing an electric bell as soon as the temperature at the point where the thermometer lies reaches 100° C. From the time that the bell rings the articles are left in the apparatus for from half an hour to one hour. From the designs of Dr. Krupin a firm of engineers in St. Petersburg has supplied a number of smaller disinfecting chambers of cylindrical form to many of the other hospitals of the city.

A simple and inexpensive method of improvising a steam disinfectant is described in a circular of the Medical Department of the Ministry of the Interior issued this year, but I have not seen one in use. It is described as follows: On the top of an ordinary kitchen or washing boiler is placed a simply made cask or barrel, which should closely fit by its lower edge to the upper edge of the boiler. In the bottom of the cask are pierced a large number of holes; in its lid, which should fit tightly, are two small holes, in one of which is fitted a cork transmitting a thermometer, the other being a very small one for the exit of steam. Inside the barrel are screwed hooks on which to hang the articles to be disinfected. The boiler being heated, steam enters the cask by the holes in the bottom, passes over the articles and escapes by the hole in the lid. The process is continued for an hour after the thermometer marks 100° C. Certain substances, such as leather and furs, are spoilt by steam, but objects made of wool, hair, down, feathers, linen, hemp, cotton, silk, cloth of all sorts, velvet or plush, such things as books if unbound, mattresses, blankets and carpets may all be disinfected in this way without injury. Objects which are injured by steam are submitted to the action of chlorine gas in a specially prepared chamber. The disinfection of wards which have been occupied by cholera patients is effected at the Alexander Hospital by thoroughly syringing the walls, ceiling and floor with a solution containing one part of corrosive sublimate and one part of chloride of sodium in 1000 of water, followed by thorough ventilation for some days. The use of a 10 per cent. milk of lime is also recommended for ceilings and walls; and for floors a 4 per cent. solution of chloride of lime or a hot solution of carbolic acid and soap, as described above. In papered rooms the paper must of course be removed before using the milk of lime to the walls. For pouring down closets, cesspools, dustbins, drains and sinks lime is chiefly used. The quantity requisite for disinfection is calculated thus: For every 100 persons in health not less than one pound of pure lime should be used—i.e., of a 20 per cent. milk of lime at least 5 lb., of a 10 per cent. at least 10 lb.; while for every 100 cholera patients ten times these quantities should be allowed. This calculation is based on the units of 1 lb. of excreta per day per head in health and of 10 lb. per head among cholera patients, and allows of one part of lime by weight to every hundred parts of dejecta.

Among the many excellent measures adopted by the St. Petersburg authorities none seems to have been more thoroughly useful than the institution of a corps of volunteer disinfectors. These men, 130 in number, were enrolled under the control of the municipal medical officers. Having first received a short course of lectures from Dr. Lipski, a prominent member of the Sanitary Commission,<sup>2</sup> and having been shown practical illustrations of the method of disinfection at the Alexander Hospital, the members of the corps were provided with detailed printed instructions as to their duties. These were principally to carry out disinfection of the rooms in the house to which they were sent, and to remove from the house to the disinfecting camera at the Alexander Hospital all clothes, bed linen, mattresses, pillows and any other movable objects that had been in contact with or soiled by the patient. The objects themselves were not

disinfected before removal, but the box, basket or sheet in which they were packed was ordered to be well moistened with either a 1 in 2000 sublimate solution or a 5 per cent. carbolic solution, from a pulverisator provided for each man. The floors and walls and all furniture were ordered to be washed with a 1 in 1000 sublimate solution, and finally with a 1 per cent. solution of soda. With the permission of the owners, any articles of small value were ordered to be burnt. It should be added that each member of the corps of disinfectors received a payment of 30 roubles (£3) per month.

Previously to the formation of the body of disinfectors measures had been taken to ensure a plentiful supply of disinfectants at a cheap rate. In June a circular of the Ministry of the Interior ordered all chemists, not only in St. Petersburg but throughout the empire, to lay in a stock of disinfectants, which they were permitted to sell only at fixed rates—the cost price without charge for dispensing (*cassa laborum*). Early in July the tax on disinfectants brought from abroad was removed by an order of the Minister of Finance.

I cannot conclude these notes without expressing my thanks to Dr. Krupin, Dr. Lipski and other St. Petersburg physicians who have kindly explained their views on disinfection or given me practical illustrations of the methods above described.

St. Petersburg.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL.

#### VOLVULUS OF SIGMOID FLEXURE WITHOUT SYMPTOMS.

By CECIL F. BEADLES, L.R.C.P. LOND. &c.,  
ASSISTANT MEDICAL OFFICER, COLNEY HATCH ASYLUM.

A MAN nearly seventy-two years of age, who had been an inmate of this asylum for two years and a half, but whose mind had been affected for thirty-two years, died somewhat suddenly under the following circumstances. He had attacks of excitement, with hallucinations of a suicidal tendency. Since admission here he had been in a more or less feeble state of health, with an aortic systolic bruit. He had been quiet for several months past, and was able to get about and do a little work. At 10 A.M. on Oct. 17th I was called to see him, as he complained of pain in the left hypochondriac region. This had only just come on; but beyond telling me of this pain he complained of nothing else, and there were no other symptoms. On examining the heart the sounds were irregular, and there was a murmur present; pulse fairly good. As his bowels had not been opened for three days, I ordered a dose of castor oil and had him put to bed. The bowels not acting, he had a simple enema a few hours later, which was only partly retained, but it brought away some fecal matter. Towards evening the abdomen became distended, and he died at 7.30 the same day. There had been no vomiting and comparatively little pain.

Post mortem the brain was such as is common in the insane, with thickening of the membrane and an excess of fluid. The heart presented hypertrophy of the left ventricle, with mitral stenosis; there was slight atheroma of the aorta above the semilunar valves; the pericardium contained about two ounces of clear serous fluid, with no adhesions. There was no other point to note beyond the condition of the intestines. On opening the abdomen there was at once seen a coil of large intestine, which was enormously distended and of a black colour. It completely hid from view all the other abdominal viscera, and had its fixed point at the brim of the pelvis on the left side, with its loop upwards. This was found to be the sigmoid flexure; it was twice twisted round itself at the fixed spot, and could be undone with ease. On removing this portion of the bowel it was found empty with the exception of a little blackish fluid, but the whole of the sigmoid flexure was of a black colour both externally and internally. The rectum and the lower part of the descending colon were empty; the rest of the intestine was slightly inflated. No stricture existed at the seat of the twist. The strangulation must have existed over twenty-four hours, and yet there was

<sup>2</sup> The Sanitary Commission has been in existence for some years in the Russian capital. It has entire control of all sanitary measures, and shares with the Hospital Commission the medical administration of the city. Special Commissions were formed on the approach of cholera to examine the sanitary condition of every building in the city and to investigate the nature of the first cases that occurred.

an entire absence of symptoms beyond some pain during the last ten hours. I mention this case as an instance of the difficulty in diagnosis so often associated with insanity.

Colney Hatch.

#### THE EFFECT OF ERGOT ON THE INVOLUTION OF THE UTERUS DURING THE LYING-IN PERIOD.

By G. ERNEST HERMAN, M.B. LOND., F.R.C.P. &c.,  
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL &c.

In the Transactions of the Obstetrical Society of London, vol. xxx., for 1888, will be found a paper by Dr. C. Owen Fowler and myself, in which observations are detailed pointing to this general conclusion: "That the administration of an ergot mixture during the first fortnight of the lying-in period appreciably increases the rapidity with which the diminution in size of the uterus goes on." This conclusion was reached by comparing the average rate of involution (a) in a number of cases, taken without selection, in which ergot was given, with (b) the average rate of involution in an equivalent number of cases, also taken without selection, in which ergot was not given. In the *Annales de Gynécologie*, vol. xxix., for 1888, p. 175, is published an investigation by Dr. Emile Blanc of Lyons, conducted in a very similar way, but which led him to the conclusion that "ergotine administered during the first five or ten days of the lying-in period exerts no favourable influence on uterine involution." Dr. Blanc's research was quoted at the time in several English journals. These two investigations seem to contradict one another. I desire to point out that they do not; but that, on the contrary, they confirm one another and show the real value of ergot in the lying-in period. The reason that Dr. Blanc's conclusion differs from that of Dr. Fowler and myself is this, that he chose the cases in which to test the effect of ergot. He took only cases of "normal delivery at full term, excluding premature labours, cases with febrile disturbance, and all cases needing any intervention" (p. 177). These cases excluded are just those in which the causes known to hinder involution are present. Dr. Fowler and I took cases without any selection, and therefore among ours were included cases in which the causes of subinvolution were present. Dr. Blanc's research shows that in a normal lying-in the uterus completes its involution as well without ergot as with it. The paper by Dr. Fowler and myself shows the beneficial effect of ergot in counteracting the causes which retard involution. Dr. Blanc's paper contains nothing in opposition to this view; on the contrary, he expressly says: "Against secondary hæmorrhage the drug maintains its position. Its action is the more efficacious the nearer the delivery." The practical conclusion is, that while in a perfectly normal lying-in ergot is not required, yet when any cause of imperfect involution is present, or suspected to be present, ergot given throughout the lying-in period will counteract its influence, will promote involution, and should be given.

Harley-street, W.

#### TWO CASES OF XANTHELASMA OF THE HAIRY SCALP IN INFANTS.

By TOM ROBINSON, M.D. BRUX., L.R.C.P. LOND. &c.

CASE 1.—An infant sent to me by Dr. Currie on Oct. 26th. It is an only child fourteen months old. The father and mother are exempt from any skin disease, and are sound, healthy parents. The child was delivered by Dr. Currie with forceps, and the nurse (an unusually intelligent woman) says in the following morning she noticed a patch in the position of the present eruption, which looked as if it had been scratched by the blade of the forceps. This patch has never disappeared, and has become more obvious as time has elapsed. It varies a good deal in colour; sometimes it will "go a deep pink for some days, then it suddenly shades off and becomes paler." The child is a breast-fed infant, is plump and healthy looking, and has excellent health. On the right side of the skull, stretching from about the middle of the sagittal suture downwards and forwards, is a streak of raised tissue, with well-defined edges, slightly scaly on its surface, and with a few, very few, fine straggling

hairs scattered sparsely over the area. It feels like ordinary skin and becomes obviously paler when stretched.

CASE 2.—This child is four years old, and has a streak corresponding in colour and appearance to the one fully related, with the exception that the plaque is on the left side and runs almost parallel to the sagittal suture. In this instance the birth was a normal one and the child is perfectly healthy.

The two cases enumerated are, in my experience, unique in the occurrence of a well-marked xanthelasmic patch on the hairy part of the skull, and in being congenital. The malady, or the symptom which is seen on the eyelids, has received enlightenment from almost every dermatologist of this century. One other feature of the two cases was the distinct statement that the patches varied in colour. At this we cannot feel any amazement, because experience shows that the ordinary plaques of xanthelasma palpebrarum vary much in their colour, and it is well known that those who suffer from migraine often betray their condition by a dark stain below or around the orbit. Dr. Currie was quite prepared to accept the doctrine that, in his case, the wash-leather patch was caused by the blade of the forceps, and had I seen this instance only I should doubtless have accepted the same explanation, but my second case negatives this opinion.

Princes-street, W.

#### SEQUEL TO A CASE OF EXCISION OF THE ENTIRE GRACILIS FEMORIS MUSCLE FOR TUMOUR NEARLY FOUR YEARS AGO.

By A. MARMADUKE SHEILD, M.B. CAMB., F.R.C.S. ENG.

THE history of this case and a description of the specimen are recorded in the Pathological Society's Transactions for 1890. The operation was performed in August, 1889, on account of a large pear-shaped tumour on the inner aspect of the right thigh. This was found to involve the gracilis muscle, and the tumour was removed by cutting the tendinous insertions of the muscle at the pelvis and knee. There were two small nodules in the lower part of the rectus femoris, and also in the cellular tissue over the adductors. The tumour was thought to be a sarcoma, syphilis having been excluded by treatment. The Morbid Growths Committee of the Pathological Society decided, however, that the tumour was a myxo-fibroma. It was noteworthy that the boy had webbed toes, as showing a tendency to congenital peculiarities. I showed this patient to some of the Fellows of the Medical Society on Monday, Nov. 7th. The boy is in excellent health, having grown and thriven well. There is an increase in the ill-defined, fibrous-feeling mass over the adductors, but the nodules in the rectus have quite gone. The loss of the muscle makes no difference to his progression, and he is a good athlete. The sequel of interesting cases is frequently as important as their early relation. Excision of muscles for tumours has generally been followed by rapid recurrence. As nearly four years have elapsed the strong presumption is that this growth is non-malignant, and the case forms an important, perhaps almost unique, exception to the general results of excision of tumours of muscle.

Stratford-place, W.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—In addition to the list of names which we published in our issue of Nov. 5th (p. 1079) of those gentlemen who had been admitted Licentiates of the Royal College of Physicians, the following have been admitted Members of the Royal College of Surgeons: W. E. Alldridge, L.S.A.; H. M. Holt, L.S.A.; S. Y. Howell, M.D., New York; A. Lockhart, M.B., Kingston, Canada; J. F. Rudall, M.B., Melbourne; A. E. Syme, L.S.A.; and S. E. A. Zichy-Woinarski, M.D., Melbourne.

MEDICAL MAGISTRATES.—Dr. Thomas Starkey Smith of Warrington; Dr. Richard Purnell of Wells, Somerset; Dr. Ptolemy Samuel Henry Colmer of Yeovil; Mr. Thomas Browne Anstie, M.R.C.S., of Devizes; Dr. Augustus Johnston of Ambleside; Dr. William Whitford of Liverpool; Mr. Joseph Kellett Smith, L.R.C.P. Edin., M.R.C.S., of Liverpool; and Dr. John Bligh of Liverpool have been added to the Commission of the Peace for the boroughs of Warrington, Wells, Yeovil, Devizes, Ambleside and the city of Liverpool respectively.

### LONDON HOSPITAL.

A CASE OF CONTRACTED KNEE TREATED BY TENOTOMY BY THE OPEN METHOD.

(Under the care of Mr. FREDERICK TREVES.)

THE advantages of the operation which Mr. Treves performed in the following case are obvious and it does not appear that so good a result could have been obtained by any other method. Although many of our readers may not be inclined to agree with the operator in all he says as to the desirability of employing the open method in other deformities where the subcutaneous method is now employed, most surgeons of experience will probably call to mind instances of contraction of the knee similar to that recorded in which this operation might have been employed with much benefit. The contraction of fasciæ and cicatrices has often proved an insuperable obstacle to complete extension after division of the tendons. Helferich,<sup>1</sup> in a case of bony ankylosis of the knee, found after the removal of a wedge-shaped piece of bone that it was not possible to straighten the limb without an amount of force which appeared unjustifiable. He therefore turned the patient on his face, made two longitudinal incisions corresponding to the lateral margins of the popliteal space, and from these divided the fascia transversely, as well as the tendons of the biceps, semi-membranosus and semi-tendinosus. Gentle manipulations now sufficed to extend the knee. The result was very satisfactory.

A woman aged twenty-one was admitted into the London Hospital under the care of Mr. Treves on March 16th, 1892, with a contracted knee. She was delicate and a member of a phthisical family. The trouble was due to tuberculous disease of the joint, which commenced four years ago. The knee was kept for seven months in splints, and after these were removed the limb is stated to have been stiff and of little use. Eight months after the splints had been discontinued an abscess formed in the outer part of the popliteal space. This in due course made its way through the skin and discharged for a period of six months. Two years ago a tuberculous ulcer formed over the outer malleolus of the affected leg and had not healed; on admission it had a diameter of two inches. The patient had not been able to use the limb for about three years. The knee-joint was a little swollen and tender, but was free from heat; it was in the position of semi-flexion and was rigid. There was a faint indication of movement sufficient to indicate that the ankylosis was not bony. The ulcer was scraped and grafted and healed readily. The limb was suspended by means of two bands, one round the ankle and one round the thigh, and a moderate weight was placed upon the knee. Not the least improvement in position followed this measure. A back splint was then applied, and by the use of it further attempts were made to straighten the joint. These were quite without effect, and as an ulcer formed behind the ankle as the result of the pressure of the splint the instrument was abandoned. More than two months were devoted to attempts to straighten the limb by mechanical means, but without the least effect. On May 27th Mr. Treves divided all the contracted tendons and bands of fascia upon which the deformity depended. A rectangular flap of skin, which included the whole of the integument covering in the popliteal space, was dissected up. The contracted tissues were thus well exposed, and were divided with precision. The skin of the flap was marked by the scars of the old abscess. The tendons of the semi-membranosus and semi-tendinosus were divided, together with the ilio-tibial band of the fascia lata. The biceps was not severed. Much cicatricial tissue occupied the hollow of the ham. This appeared to be the principal cause of the contraction, and

was divided to a considerable depth. The limb was brought into the position of full extension without the application of any force. The flap was secured in place by sutures. An anterior metal splint was applied, and by means of this the limb was suspended. The wound healed by first intention and without any rise of temperature. A back splint was applied on June 2nd, and later on the limb was secured in plaster. The patient was discharged cured on July 9th. The limb was then straight. The joint admitted of a little movement, and the patient could walk—for the first time for nearly four years—without artificial aid of any kind.

*Remarks by Mr. TREVES.*—The early operations of tenotomy were all performed by the open method, by a free incision or the forming of a flap and the deliberate division of the exposed tendon or band. The introduction of the subcutaneous method was an improvement, inasmuch as it avoided the dangers of an open wound, which were at the time considerable. The introduction of aseptic surgery has rendered the precaution of a subcutaneous incision quite unnecessary; and as it is desirable that a knife should never be used in the dark and that a surgeon should know and see precisely what he is cutting, it would be well if the open method were once more to become the regular practice. In dealing with certain tendons, such as the tendo Achillis, I still carry out the subcutaneous incision, because the division can be perfectly made through a small puncture and an operation would need be no larger than mere efficiency requires. With regard to other tendons, such as the sterno-mastoid, I have returned to the older method of operating. The present case serves to illustrate the value of this method. A subcutaneous operation in this instance would have been dangerous, uncertain and most imperfect. After the prominent tendons—including the biceps—had been divided the remaining adhesions would have been "broken down." This violent measure involves a deeply placed lacerated wound and is apt to be followed by much inflammatory reaction and by subsequent stiffening of the joint. The cicatricial tissue left in the track of the abscess appeared to offer a greater resistance to the correction of the deformity than did the prominent and easily reached tendons.

### ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A CASE OF FRACTURED HUMERUS WITH INJURY TO THE MUSCULO-SPIRAL NERVE.

(Under the care of Mr. F. PAGE.)

THE following is a short but interesting contribution to the series of injuries of the musculo-spiral nerve with fracture of the shaft of the humerus, which have required operation for the relief of resulting loss of function. The nerve was not apparently injured by the fractured ends, nor was it involved in the callus, as so frequently has been found on examination, but was covered and bound down by the periosteum and regained its functions when freed from it. The effects of the compression in this case were much the same as those met with when the trunk has been involved in callus, where, as Trélat<sup>1</sup> points out, motor and sensory changes are more common than those of nutrition. After the operation the nerve rapidly recovered its functions, more quickly than is usually found when callus has produced the compression; in such cases improvement is often delayed. For the notes of this case we are indebted to Mr. R. Sterling, house surgeon.

A miner aged thirty-eight was admitted under the care of Mr. F. Page on May 29th, 1892, complaining of inability to use his left arm. Four months previously while walking along a railway line he was knocked down by an engine and suffered a simple fracture of the arm. It was put up in splints and maintained in that position for five weeks, when it was found that his forearm and hand were practically useless. The seat of old fracture could be felt at the middle of the humerus. The upper end of the lower fragment projected to the outer side and behind about the position of the middle of the musculo-spiral groove. The muscles on the external aspect of the forearm were much atrophied. The patient was unable to extend his wrist, fingers or thumb, and sensation was less acute. The faradaic current was applied for a week, but without any effect. On June 14th a vertical incision was made about four inches and a half in length in front of and parallel

<sup>1</sup> Report of the Congress of German Surgeons: Arch. für Klin. Chir., Berlin, 1891. Sajous, vol. iii., G. 18. 1892.

to the external supra-condyloid ridge of the humerus. This was carried down to the bone over the seat of the fracture. The radial nerve, which was given off abnormally high, was first exposed. On following this upwards the main trunk of the musculo-spiral was discovered adhering firmly to the bone, covered by the periosteum but free from entanglement in the callus. The nerve was freed from its attachment, the divided muscles sutured and replaced beneath the nerve, which now took a new course in a muscular bed. The superficial structures were sutured and the wound dressed without drainage. A week after the operation the patient was able to extend his wrist, but could not move his fingers. On July 4th he left the hospital with power to move his fingers. He returned in about six weeks with his hand and forearm as strong as the other.

## Medical Societies.

### MEDICAL SOCIETY OF LONDON.

*Tuberculous Ulceration of Pharynx treated by Lactic Acid.—Left Inguinal Colotomy.—"Caisson" Work in Bladder Surgery.—Radical Cure of Hernia.—Pelvic Bony Tumour associated with Osteo-arthritis of Hip.—Leprösy improved under Treatment.—Fusiform Carotid Aneurysm.—Cystic Tumour of Auricle.—Ulceration of Ears.*

A CLINICAL EVENING of this Society was held on Nov. 14th, the President, Mr. Hutchinson, in the chair.

Dr. PERCY KIDD showed a case of severe Tuberculous Ulceration of the Pharynx, which had been successfully treated by lactic acid. The patient, a woman aged forty-one, at the present time showed a large cicatrix on the back of the pharynx; there were still a few small nodules at the side of the scar and at the back of the tongue. She presented signs of pulmonary tubercle at the beginning of the year, and later the throat trouble commenced. Before treatment was begun there was diffuse ulceration of the whole of the back of the pharynx, the surface being pale and grey, dotted with bright red points like tubercles and coated with a tenacious secretion. It was intensely painful, swallowing being almost impossible. The surface was thoroughly cocaineised and lactic acid was freely applied, first in a solution of 50 per cent. afterwards the pure acid being used. It was only after fourteen applications that evidence of healing was observed; then the pain soon ceased and the improvement rapidly advanced. The most favourable case for this treatment was an ulcer without thickening of the submucous tissue. If there were induration not broken down the surface should be touched with the cautery and the acid then rubbed in. Great patience and perseverance were necessary to produce good results. The ulcer had not been examined for bacilli, though they were found in the sputum. He had seen four cases cured by the lactic acid treatment, and he referred to one case of undoubted tuberculous ulceration in which a spontaneous cure took place.—The PRESIDENT related a case under his own care in which there was a large ulcer of the soft palate quite superficial, and the diagnosis lay between epithelial cancer and tubercle. It was treated by the liberal use of Paquelin's cautery on three occasions, and it healed. In another case of extensive ulceration a fatal result followed extension of the pulmonary trouble.

Mr. GOODSALL exhibited a clerk aged forty-seven on whom he operated in January last for Fissure of the Anus, and he then found a tumour growing from the sacrum and extending into the pelvis on the left side. At the end of October the abdomen began to show signs of distension, and on Nov. 10th a left inguinal colotomy was performed. Two days later the bowel was opened by a linear incision, and a month afterwards he left the hospital. He had since increased much in weight, and at the present time the characters of the tumour appeared to be unchanged.

Mr. GOODSALL likewise showed a French polisher aged seventy who had been the subject of Cancer of the Rectum. He had lost flesh for two years and had passed blood from the rectum for about three months, there being about six motions daily, accompanied by prolapse. The carcinomatous growth occupied the posterior three-fifths of the rectal wall. It began about one inch above the anus and extended upwards for three

inches, being freely movable. Left inguinal colotomy was performed on June 14th, and a longitudinal incision was made into the bowel two days later. On June 28th the lower end of the rectum was removed together with the growth, a small incision being made behind the anus, a pair of blunt-pointed scissors introduced to separate the rectum from the surrounding tissues, and section of the gut being performed by a wire écraseur. The patient left the hospital thirty-six days after the removal of the growth. The site of the anus was occupied by a scar and the man had since gained in weight.

Mr. HURRY FENWICK gave a description of what he called "Caisson" work in Bladder Surgery. To remove a small growth he made a limited anterior incision into the bladder and then sunk in an open cylinder somewhat like a Ferguson's speculum; this being pressed against the floor of the bladder over the growth, the water was sucked out, and he operated under the direct influence of a powerful electric light. For these sessile growths under the old method a large incision into the bladder was required, together with a big rectal bag. With the method he demonstrated it was not only possible to remove the growth, but also to apply the cautery with exactitude. He exhibited two patients from whom he had removed sessile villous growths by this method.—Mr. SWINFORD EDWARDS had found the method answer well in a case of vesicular carcinoma; it would also be useful for attacking tuberculous and other ulcerations of the bladder.

Mr. LOCKWOOD showed a man aged forty years who had Right and Left Inguinal Hernie, and also an Umbilical Hernia. He also suffered from genu valgum. These conditions indicated a general defect which would usually forbid operation. However, the hernie could not be retained by the largest and most powerful trusses, and the man could not follow his employment. The right inguinal hernia was the largest and contained the cæcum, vermiform appendix and some ileum. The operation exemplified that even such large ruptures as this could be successfully treated through a small skin incision along the length of the inguinal canal, and that the wound could be closed without drainage, and would heal under a single dressing. On the right side the opening in the abdomen was very large and direct, and therefore it took a much longer operation for its closure, and it would probably be less secure than the left side. Here the hernia was smaller and the conditions more favourable. A smaller wound was required, and it also got well under one dressing. Another point exemplified was the occurrence of orchitis when the conditions were unfavourable. The spermatic veins were adherent on the right side, and had to be stripped off, causing subsequent phlebitis, followed by some orchitis and acute hydrocele. On the left side there were no adhesions, and no ill results followed. The operations had both caused a great thickening of the abdominal wall in the hernial regions, where many silk sutures had been inserted; but, nevertheless, it would probably be wise to give the patient a light truss as his hernie were acquired and associated probably with prolapse of the mesentery and other organs.—Mr. SHEILD inquired as to the suture employed. He had had difficulty with buried sutures, small abscesses being sometimes formed with extrusion of the ligature knot.—Mr. S. EDWARDS advocated the high incision on account of the easier separation of the constituents of the cord that was then possible.—Mr. LOCKWOOD, in reply, said that he used properly prepared silk for his buried sutures.

Mr. G. R. TURNER showed a man aged thirty-eight who was admitted to the Seamen's Hospital in April last with Eversion and Shortening of the Right Limb. There was no history of an accident, and the joint moved freely and painlessly. It had been progressing slowly for six months. He had removed a bony swelling as big as a Tangerine orange in connexion with the ascending ramus of the ischium, and he found another bony tumour lying loose in the cellular tissue. The shortening of the limb had rapidly increased, accompanied by some difficulty of movement. The limb regained its proper length on application of extension, and the shortening therefore appeared to be due to absorption of the head of the bone. He regarded the case as one of Charcot's disease. There was loss of patellar reflex, the gait was unsteady, but there were no gastric symptoms and no numbness. There was no history of syphilis.—Mr. ALLINGHAM referred to a similar case of bony growth associated with hip-joint trouble in which the only symptom of tabes was the Argyll-Robertson pupil, but the patient later developed typical locomotor ataxy.—Mr. WALSHAM con-

sidered these bony growths unconnected with the joint not uncommon.

Dr. ABRAHAM re-exhibited a lad whom he had shown last year suffering from Leprosy, which had improved under treatment. The diagnosis had been confirmed on his arrival from Demerara, and since then there had been a marked retrogression in the manifestations of the disease. He had had chaulmoogra oil, plasters of chrysarobic acid had been applied locally, and at present he was taking cod-liver oil together with sixteen grains daily of gynocardate of magnesia.—The PRESIDENT referred to several cases under his care which he had treated on a simple plan with nux vomica, small doses of arsenic, together with a plentiful nutritious diet, and all had improved. He had very little faith in the drugs used, and believed the more important factors to be the climate and the diet. All the cases he believed to be absolutely non-contagious.—Dr. HERON said that those who believed the disease to be contagious had asserted that it always spread from those who had open sores, which had never been the case with the patient under discussion. He doubted if there was at present any evidence of medical treatment being of material value in the cure of leprosy.

Dr. HERSCHELL showed a woman aged seventy with a Pulsatile Tumour of the Neck, which she had noticed for three years. He believed it to be a fusiform dilatation of the carotid, and the only symptoms attributable to it were occasional fainting fits.—The PRESIDENT remarked that these cases were not uncommon and did not usually lead to mischief.

Mr. SHEILD showed a Cystic Tumour of the Auricle in a man aged forty-four, which had existed since 1864. He believed it to be of sebaceous origin.

Mr. SHEILD likewise showed a youth aged seventeen the subject of Ulceration at the Edges of the Ears, which had come on in the summer. There were no signs of Raynaud's disease.—The PRESIDENT said he had published a series of such cases, which he called "sun blain," and which were like "chilblain lupus." The ears were often so eroded that they looked as if they had been eaten away by rats.

## CLINICAL SOCIETY OF LONDON.

*Sequel to a Case of Tuberculous Peritonitis.—Hyperplastic Phlebitis.—Lumbar Nephrolithotomy.—Double Emphyema.*

AN ordinary meeting of this Society was held on Nov. 11th, the President, Sir Dyce Duckworth, being in the chair.

Mr. LAW FORD KNAGGS (Leeds) read a paper in which he described the appearances noted at an operation for Ventral Hernia five and a half years after laparotomy had been performed for tuberculous peritonitis. The case had been recorded in the Clinical Society's Transactions (vol. xxi.), and at the first operation the intestines, mesentery and parietal peritoneum were covered with myriads of pale pink, gelatinous-looking tubercles, as large as hemp seeds, thickly and universally distributed. The patient, who had grown into a strong and healthy young woman, reappeared in October, 1891, with an irreducible omental hernia at the site of the abdominal incision. This was successfully operated upon in November. The sac and contained omentum presented nothing unusual in appearance. The omentum that prolapsed through the hernial aperture during the operation was quite healthy. The parietal peritoneum inside the ring felt quite smooth to the finger, and a coil of small intestine, which could be well seen through the opening, was glossy and looked like perfectly healthy bowel. No signs of tubercle nor any evidence of the tuberculous condition that had existed five and a half years ago were detected. These observations, though necessarily slight and imperfect, were recorded because they threw some light upon what became of peritoneal tubercles when the patient got well.—Mr. HOWARD MARSH gave some details concerning a case in which laparotomy was performed for tuberculous disease of the peritonium. Ascites was present, and distended veins coursed over the surface. A few days after the operation the patient improved, and she was discharged cured in two months, the abdomen then being normal in appearance. He referred to the peculiar behaviour of peritoneal tubercles, and suggested that the subject was worthy of being specially discussed. In some cases the tuberculous nodules undoubtedly necrosed and disappeared.—Mr. BRUCE CLARKE referred to a case in which he had performed laparotomy for peritoneal tubercles, and the sac was irrigated, the result being complete recovery. Eighteen months later ovariectomy was per-

formed on the same patient, and no trace of tubercle could then be discovered. In another case, in which laparotomy was urgently indicated, it was declined and the patient recovered.—Mr. LANGTON remarked that it was by no means rare to find omentum protruding into a ventral hernia; he had met with an average of about four or five cases a year. It usually presented itself in the lower part of the incision. He referred to a case in which there was protrusion of omentum and intestine through a part of the wall not opposite to the line of suture.—Dr. GLOVER mentioned the case of a boy between eight and ten years of age who presented all the appearances and symptoms of peritoneal tubercles. Dr. Goodhart, in consultation, confirmed the diagnosis, and he discovered what were regarded as hard masses of tubercle by rectal examination. The lad got quite well, however, without operative interference.—Dr. GOODHART said that the peculiarity in the case under discussion was that the peritoneum recovered its perfectly normal appearance. The existence of spontaneous cure of tuberculous peritonitis was undoubted from a medical point of view. He related a case which he had examined post mortem for Dr. Habershon of a lady who some years before had been under the care of Dr. Stewart for tuberculous peritonitis. At the necropsy but little trace of tubercle could be found, but there were a few scattered caseating masses with numerous adhesions.—Dr. BARLOW remarked that the cases which seemed to do best were those in which a moderate amount of fluid was present. The cases with miliary deposit of tubercle in the peritoneum often recovered with or without operation. The cases not to be attacked surgically were those in which there were caseating masses in the omentum with dry peritonitis and extensive adhesions. Surgical treatment of these had been hitherto most unsuccessful.—Dr. HADDEN stated the result of a post-mortem examination in the case of a child whose abdomen had been opened two months previously and miliary tubercle observed to be present. No trace of this condition was found at the necropsy, and the glands were not enlarged or caseous.—The PRESIDENT remarked that in no part of the body did tuberculous lesions fare better than in the peritoneum, and he concurred in the opinion that those cases were the most favourable in which some ascites was present.—Mr. KNAGGS, in reply, said that bacilli had not been searched for. The object of his paper was to demonstrate the fact that disappearance of tuberculous deposit might occur and might leave the peritoneum normal in appearance.

Dr. HANDFORD described the case of a man aged thirty, with intermittent albuminuria, cardiac hypertrophy, high vascular tension, general dilatation of the superficial venules, obliterative endarteritis and phlebitis, the latter nearly occluding the saphena and other large veins. The patient was a spare dark man, showing signs of degeneration in his greyish hair and an arcus senilis in each eye. He suffered much from migraine. He had been failing for two years and lost a stone in weight. He denied having had gonorrhœa or syphilis, and there were no signs of the latter. He complained of pain in the left loin. The apex beat of the heart was heaving and the first sound was distinctly reduplicated. The radials were thickened and the tension was very high. Both internal saphena veins stood out very prominently and to the touch resembled tendons. There were no adhesions, and the veins could be rolled quite freely under the finger, but could not be flattened. In the horizontal position it was not possible to detect any flow of blood along the lower third of the main trunk on either side; but with the patient standing there appeared to be a slight movement of blood in them. A similar condition affected the external saphena veins, most of the branches of the internal saphenas, the radial, ulnar and cephalic veins. There was no history of preceding thrombosis or of œdema. Under the use of iodide of potassium and mercury the vascular tension fell to normal and the induration of the veins greatly diminished, but did not disappear, while the circulation through them became much more free. The albuminuria persisted in the intermittent form.—Dr. HADDEN mentioned the case of a man between fifty and sixty years of age who for years had been liable to recurrent attacks of inflammation, blocking the veins and arteries much as had happened in the case described by Dr. Handford. He referred to cases of obliterative arteritis reported by Mr. Gould and himself, in which there was no syphilis or renal trouble.—Dr. MORISON referred to a case in which there was a similar condition of the veins of the limbs, and in which, after suspected obliteration of the external iliac veins, a large surface collateral circulation developed. Removal of an elongated uvula for expectoration of blood was

followed by much trouble in stopping the bleeding; there was slight albuminuria and the temperature was abnormally low.—Dr. HANDFORD, in reply, said that the case was a typical example of arterio-capillary sclerosis which had extended to the larger vessels.

Mr. DAY read notes of a successful case of Lumbar Nephrolithotomy in a woman aged thirty-two, from whom a calculus weighing 1331 grains was removed. The history was that of about fifteen years' growth, with, in the later stages, pyonephrosis. The principal feature of the case was the division of the operation into two stages, in the first of which free vent was given to the pus and a large branch of the stone removed, and a fortnight afterwards the wound was extended and the kidney thoroughly cleared of stone. She made a good recovery and was in perfect health, but a sinus remained in the loin. Reference was made to several similar cases, though none of such a large size, with successful results.—Mr. HOWARD MARSH was in agreement with Mr. Day that it was best to remove the stone without removing the kidney, which might have been difficult through the lumbar incision.—Mr. DAY, in reply, said that recently, when removing a large kidney for tumour, he did so through a lumbar incision, continuing the latter forward to the linea semilunaris. The procedure was carried out without difficulty, and the patient did well.

Dr. WALTER CARR related a case of Double Empyema treated by drainage. The patient was a boy aged seven years and three-quarters, who was admitted to the Victoria Hospital for Children, Chelsea, on Jan. 1st, 1892, suffering from double empyema. The illness had commenced suddenly on Dec. 13th, 1891, with symptoms pointing to pneumonia. On admission the boy had urgent dyspnoea; respiration 72, very shallow; pulse 176, very small; temperature 102°. Dulness and distant bronchial breathing over the lower part of both lungs. Pus was found on both sides with the exploring syringe. Eight ounces and a half of pus was withdrawn from the right side by the aspirator, and as it would not escape readily from the left side, on the following morning a piece of the left eighth rib was excised by Mr. Naish, the house surgeon, under local anaesthesia induced by cocaine, and seven ounces of pus escaped. A large drainage-tube was inserted. The boy stood the operation well. After this the child's condition improved somewhat, but the temperature oscillated between 99° and 101°, the pulse and respiration both remained very high, and diarrhoea was troublesome. Four days after the first operation a portion of the right sixth rib was removed under cocaine as before, eight ounces of pus evacuated, and a large tube inserted; there was much more collapse than after the first operation. During the next three or four weeks the temperature was 98° and 103°, owing in part to the development of a double purulent otorrhoea, and partly also perhaps to the original pneumonia not having entirely subsided. However, the child slowly improved, the temperature became normal by the end of January, the diarrhoea ceased and the lungs expanded. The left tube was finally removed on March 10th, but for some weeks previously it had only drained a narrow sinus. The right lung took longer to expand, and the tube was only left out on April 5th. In March, during convalescence, the patient had a curious and unexplained attack of hæmoglobinuria, lasting about a week; the urine was very dark, gave the reaction for blood pigment, and showed a copious dark granular deposit, with about one-third albumen on boiling. Under the microscope a few red discs and granular casts were seen. No history was obtained of any similar previous attack, and there had been no exposure to chill. The boy was sent to Margate on April 13th, the left lung being completely expanded, and the right also, except a small portion at the base. The heart was not displaced. Eventually both lungs expanded completely, and the boy got perfectly well in every respect. Reference was made to other recorded cases, and especially to a paper on a similar case read by Dr. Sidney Coupland and Mr. Pearce Gould before the Society in December, 1890. The present case entirely confirmed the conclusions at which they had arrived, particularly as to the advisability and safety of treating these cases by free drainage, provided that if possible an interval of a few days were given between the operations on the two sides, in order to avoid the danger of excessive shock.—Mr. L. DUNN said that some years since he operated on a case of double empyema with seven days' interval with a successful result, and he referred to a similarly fortunate case in the practice of a friend.

## PATHOLOGICAL SOCIETY OF LONDON.

*Special General Meeting.—Epitheliomata on the Legs of a Fowl.—Genito-urinary Organs of a Pseudo-hermaphrodite.*

A SPECIAL GENERAL MEETING of this Society was held on Nov. 15th, Mr. H. T. Butlin, Vice-President, in the chair.—The meeting proceeded to the consideration of certain alterations in the laws of the Society proposed by the Council. After much discussion it was agreed that such members as resided within ten miles of Charing-cross should be considered as resident members, that every person elected a non-resident member should pay a life subscription of three guineas, and that the scale of composition fees for resident members should be readjusted.

Mr. J. JACKSON CLARKE showed the Feet of a Fowl with numerous ulcerated tumours of epithelial origin. The structure of the growths was difficult to make out on account of imperfect preservation, but it strengthened the suspicion awakened by the naked-eye appearances that the condition was allied to that described by Darier in man as general follicular psorospermosis.

Mr. J. JACKSON CLARKE showed for Mr. Herbert Page the Genito-urinary Organs of a female pseudo-hermaphrodite who died aged seven. There was a perforate penis, besides a blind recess at the normal site of the female urethra. The bladder had on each side a large sacculus into which the ureter opened. Mr. Clarke considered that the specimen showed that the greater part of the female urethra was formed from a part of the urogenital sinus which was not utilised in the formation of the male urethra.

The following card specimens were shown:—

Dr. E. C. PERRY: Colloid Carcinoma of Stomach.

Dr. H. D. ROLLESTON: (1) Epithelioma of Pharynx; secondary growths in bone. (2) Osteo-arthritis of Joint between First and Second Pieces of Sternum.

Recent Specimens:—

Dr. H. P. HAWKINS: Fat Necrosis from a case of Peritonitis.

Dr. A. F. VOELCKER: Malignant Tumour of Jejunum.

## OBSTETRICAL SOCIETY OF LONDON.

*Adjourned Discussion on Abdominal Section in Pelvic Peritonitis.*

THE adjourned discussion on Dr. Cullingworth's paper took place on the 2nd inst., Dr. J. Watt Black, President, in the chair.

Dr. GERVIS began by expressing the opinion that if the title of the paper were carefully considered the objections to it stated by some of the speakers at the last meeting would be much lessened, for operative measures were not proposed in all cases of pelvic peritonitis, but only in certain cases, and these would appear from the third of the series of propositions Dr. Cullingworth had drafted to be cases of recurrent peritonitis associated with "distinct swellings in the posterior quarter of the pelvis," and with this proposition he (Dr. Gervis) could not hesitate to agree. It was true that many of these cases were not fatal, but in many there was more than one element of risk, and in all there was much positive suffering and more or less permanent invalidism and disablement, for the relief of which ordinary medical measures were of little avail. On the general question of abdominal section in cases of hæmatocele, he thought it was rarely called for apart from the occurrence of suppuration. He was disposed to agree with Dr. Williams' remark with reference to operation in cases of salpingitis associated with tubercle. As to some of the occasional sequelæ of the operation, he thought that they were hardly of sufficient importance to outweigh the great gain attained by the procedure in question.

Mr. MAYO ROBSON (Leeds) preferred to discuss the subject of the paper as a general surgeon on general principles, feeling sure that it was seldom necessary to depart widely from such in treating these cases of localized peritonitis. If we have an abscess in the neighbourhood of the cæcum we do not hesitate to open and drain it, lest it burst into the general peritoneal cavity, and why should there be any argument as to the propriety of dealing with a pelvic abscess on similar principles? If a patient suffer from recurrent attacks of perityphlitis, so-called, and the disease depend on recur-

ring inflammation of the appendix vermiformis, we do not hesitate to remove the appendix. Some months ago he saw a young patient suffering from frequently recurring attacks of pain over the pylorus, associated with emaciation and not yielding to medical treatment; he diagnosed adhesions over the pylorus following gastric ulcer, opened the abdomen, separated the adhesions, and the patient is now robust and well. Why should it be thought unwise in recurrent pelvic peritonitis to separate adhesions as a rule far more extensive than in the case named? Where life is endangered surely no one can dispute that an operation which gives a good chance of cure and which need have a mortality of not more than 5 to 7 per cent. is unwise. He would prefer not to operate in cases of hæmatocele unless suppuration were indicated. He handed round a printed record of all his hospital and private cases (sixty-five in number), giving details as far as possible on Dr. Cullingworth's lines. There were two deaths referable to the operation (3 per cent.). He had several times opened and drained pelvic abscesses through the peritoneum, but he agreed with Dr. Cullingworth that such a procedure is not so satisfactory as removing the abscess sac, which is frequently a dilated tube. He disagreed with those speakers who argued that such abscesses were best treated from the vagina. He agreed with all Dr. Cullingworth's conclusions in the main, although probably differing in the details. He disagreed with those who argue that this class of cases very seldom ends fatally if left to nature, as he had known a number do so. Healthy organs were never removed, and if the disease was limited to one side the other appendage was not removed. He now never removed the ovaries for the cure of nervous symptoms.

Mr. KNOWSLEY THORNTON said he had studied Dr. Cullingworth's paper and tables carefully, with the result that he was deterred from sanctioning or performing these operations. First, there was the terrible mortality of 18 per cent., a mortality which could not in any way be justified by the mortality of the diseases themselves when left alone. There was the extraordinary fact that nearly half the cases were incomplete. Six had sinuses and four herniæ. The latter, in spite of what Dr. Gervis had said, were very real miseries, and often far greater sources of weakness and pain than the diseases which the operations were undertaken to cure. He had taken the trouble to go over his own case-books, and from that he had in the whole of his practice, extending over nearly twenty years, operated eighty-seven times in this class of case with six deaths (about 7 per cent.), and it must be remembered that all his early work was done in times far different from the present. In the whole series he had only three incomplete cases, and his mortality would have been only half what it was if he had not resolutely completed three other cases, recognising the fact that these operations, if only partial, would be far better for the patient's sake if they had never been attempted. He believed that if only urgent and proper cases were operated upon the mortality would never fall much below 6 per cent. Were the diseases for which the operations were undertaken as fatal even as this? He doubted it. He had never seen a fatal case himself. Dr. J. Williams had seen two. Surely this was not much for their united experience. Then, again, how few fatal cases were ever published? He would also greatly discount recurrent peritonitis; much was called local peritonitis which had no claim to be so named. He doubted the wisdom or justifiability of surgical interference in hæmatocele unless it had suppured, and he thought many collections of pus in the pelvis were much better opened per vaginam, where drainage was not against gravity. He criticised Dr. Cullingworth's concluding propositions, and asked on what grounds he said that salpingitis was a painless affection. The double or complete operation he was inclined to think more satisfactory in the long run in most cases. He did not wish to pose as the opponent of all operative interference in these cases. Some operations were, however, failures in point of cure; others, and the majority, were, however, very successful. He would not, however, like it to go forth from the Obstetrical Society that Dr. Cullingworth's propositions were commended by all.

Mr. JOHN W. TAYLOR (Birmingham) heartily agreed with the general tenour of every one of Dr. Cullingworth's propositions. Whether the classification of the cases on which they are founded was a wise one or not, he was glad to recognise that all the cases under discussion were unmistakably inflammatory, and all resulted in decided peritonitis. There was no question in this controversy of the removal of cirrhotic or cystic ovaries, and the discussion was at least

narrowed down to the question of removal when distinct peritonitic symptoms were or had been present; and on this question he was largely in agreement with Dr. Cullingworth. The only fault he had to find (if he might presume to say so) was that the propositions dealt with too wide a subject. In his own experience he found that gonorrhœal inflammatory diseases of the appendages is a special disease due to a specific contagion, possessing many features in common with the inflammatory affections of the appendages, but quite distinct from them in its course and results. Virginity by no means precludes the possibility of this disease. Not a few of the cases of purulent vulvitis and vaginitis met with in early childhood are found to be due to accidental infection; and such cases may result in typical gonorrhœal pyo-salpinx years afterwards, when the primary disease has been lost sight of. If the disease then be a distinct and special one, equally distinct and definite should be the rules governing its treatment. It is to this disease (because it is a contagious one and the uterus as a centre of contagion is always left behind) that the advice of complete removal of the appendages on both sides specially applies. If operation be required at all in this disease it needs to be thorough. All inflammatory affections of the appendages are not gonorrhœal. The naked eye characters may be almost identical. There may be extensive adhesions, abscess of ovary, or a limited purulent peritonitis around the appendages. Then he believed the nature of the case was, and its treatment should be, radically different. Here, if the inflammatory affection were limited to one side of the pelvis, there would be no need to remove the appendages of the opposite side. His own practice on diagnosing a case of acute or subacute tubal disease, unless there be special urgency, is to send the patient to bed for a fortnight or a month, giving bromides. If at the end of this time there be no improvement an operation is usually necessary. The circumstances of the patient are sometimes of first importance.

Dr. HEXWOOD SMITH said Mr. Thornton had referred to ventral hernia as of frequent occurrence and grave import, but such an accident did not often happen and was not to be weighed against the chronic invalidism and pain that the operation was intended to obviate; and as to calling it an operation of "expediency," it was in most cases an operation of necessity. He entirely agreed with Dr. Cullingworth's sixth proposition that "it is safer to attack cases of pelvic suppuration from above than from below." Some of those who had attended the Congress at Brussels had seen M. Segond do Pean's operation on a case of ovarian abscess. He first of all removed the uterus morcellement and then proceeded to puncture the abscess—a method they had considered wholly unjustifiable. M. Segond contended that the removal of the uterus caused the uterine appendages to dwindle; but they would require a large number of necropsies, after a long interval of time, before they would be in a position to prove such a statement. Then, again, with regard to Dr. Champneys' statement as to drainage per vaginam being more favourable owing to gravity, they must remember that when a woman was lying supine the drainage-tube was not wholly in a position downwards. Mr. Thornton had said that few patients died in these cases if left alone. He would like to know on what grounds Mr. Thornton made that most extraordinary statement.

Dr. GRIFFITH wished to draw attention to the frequency with which some speakers referred to "gonorrhœal" salpingitis, as if this were a cause easily ascertained, his experience being that it was neither easy nor common to obtain satisfactory evidence of the gonorrhœal origin of pelvic inflammations, and that these most frequently occurred after abortion, labour, and various methods of intra-uterine treatment, especially after the use of intra-uterine pessaries and tents, in all of which the probable cause was a septic one.

Mr. SKENE KEITH drew attention to the length of time which often elapsed before recovery was complete after these operations. Patients were frequently under the impression that after operation they would be well in a few weeks. If, however, they were made to understand that it might be months before their return to health would be perfect, they would be more willing to try in the first place what rest would do. At the end of six months comparatively few of these operation cases were quite well, while at the end of two years the results would be found to be very satisfactory.

Dr. CULLINGWORTH, in reply, said the object of the paper was to show that, underlying many cases of pelvic peritonitis, there was definite disease which could only be

properly dealt with by surgical means. The words "certain cases" in the title were intended to limit the discussion to those cases in which there was a definite swelling in one or both sides of the pelvis. It was in those only that he advocated and practised abdominal section. It was one of the surprises that a series of cases like this brought out, that the source of the inflammation in many cases of recurrent pelvic peritonitis is suppurative of an unsuspected ovarian cyst. Such cases have hitherto been diagnosed and classified under the vague heading of pelvic abscess. Amongst the fifty cases tabulated there were no fewer than nineteen in which new growths were present. Of course, as experience was gained one could often predict, with an approach to certainty, that in the midst of a given pelvic swelling, such and such a definite mass of disease would be found. He would refer any of the Fellows who were interested in this question to a series of six cases of abdominal section for peritonitis due to suppurative of previously unsuspected cysts of the ovary, which happened to be all under treatment at the same time, and which had been reported in THE LANCET for the first two weeks of the current year. There would be found in that series two remarkable cases in which the patient was suddenly seized with symptoms of acute pelvic peritonitis. It was determined to open the abdomen in order to avert, if possible, a fatal termination, which otherwise seemed inevitable. Neither of the patients knew anything of any tumour, yet on opening the abdomen each was found to have not one, but two, large suppurating ovarian cysts. In connexion with the question of mortality it should be stated that of the fifty patients fifteen were so ill at the time of operation that it was evident to all who saw them that a fatal issue was rapidly approaching. Of these fifteen four died; of the other five patients who died four were totally incapacitated for work of any kind, and the fifth, though able to do light work occasionally, was laid aside by an attack of pelvic inflammation every few days. It was not the case that his later and more successful operations were undertaken for less serious conditions, or were in any degree less complicated or less difficult than his earlier ones. Dr. Williams had referred to a paper by Schmalzfuss as containing the only reliable account with which he was acquainted of the proportion of cases in which pain persisted after these operations. He held in his hand a copy of Schmalzfuss's paper. The title of it was "Castration for Neuroses." The object of Hegar's operations there recorded had nothing in common with the object of the operations as described in the paper. When an operation was undertaken for the relief of pain, irrespective of any obvious lesion, the operator must be prepared for disappointment. On the other hand, where there was obvious disease extirpation of the source of inflammation invariably cured the patient, provided she survived the operation. The occurrence of a little subsequent pain does not constitute a failure. Dr. Williams had noted that two cases required a second operation. In both cases the fault lay not with the operation, but with the operator. The cases which Mr. Doran held up as the few examples on the list of really good surgery were just those of which he (Dr. Cullingworth) was not particularly proud. They were cases of simple evacuation and drainage of suppurating cavities where the source of suppurative was not removed. Mr. Doran expressed surprise that in Case 39, where there was a communication between the suppurating cyst and the rectum, separation and removal of the cyst were accomplished without the occurrence of a faecal fistula. If Mr. Doran would refer to Case 25 he would find the same good result followed a similarly bold procedure there, and he would also note, on referring to Case 48, that a communication with the vagina gave no further trouble after the removal of the adherent cyst. The necessity of invoking the aid of gravitation in order to obtain efficient drainage was a notion that had long since been exploded. Experience had abundantly proved that the force of intra-abdominal pressure was amply sufficient to drive all the fluid out of the abdomen as fast as it accumulated, if only a means of exit were provided. Then Dr. Champneys said that a number of these cases were ordinary cases of pelvic abscess. If by that he meant abscesses in the connective tissue he was mistaken; there was no such case in the list. If he meant pelvic suppurative, of whatever kind, of course it was open to Dr. Champneys to adopt the vague name of pelvic abscess if he preferred it. Most of Dr. Playfair's criticisms were based on a classified list of the various conditions found when the abdomen was opened. When Dr. Playfair came to read the full details he would be the

first to acknowledge that in almost every case there were good grounds for operating. He was glad to hear the remarks of Mr. Mayo Robson, for he had looked at the question from the point of view of a general surgeon, and had supported the contention of the paper as being in accord with ordinary surgical principles. Turning to the speech of Mr. J. W. Taylor, he was under the impression as he listened that he was telling the story of Case 14, so similar was that story to the one Mr. Taylor related.

The following specimens were shown:—Dr. Cullingworth, Pyo-salpinx; Dr. Aust Laurence, Ruptured Tubal Gestation; Dr. Leith Napier, Microscopic Double Oophorectomy; Dr. Galabin, Dermoid Cyst.

## OPHTHALMOLOGICAL SOCIETY.

*Conjunctivitis set up by Flies.—Hyperplastic Subconjunctivitis.—Intra-ocular Injection of Antiseptic Solutions.—Intra-ocular Absorption of Iodoform.*

An ordinary meeting of this Society was held on Nov. 10th, Mr. Henry Power, President, in the chair.

Dr. BERRY (Edinburgh) read brief notes of two cases of Conjunctivitis set up by Flies: 1. An old man in whom severe inflammation of the conjunctiva, accompanied by extensive corneal ulceration, came on within twenty-four hours of his having been stung in the eye by a fly which had apparently risen from a dunghill. In addition to the local disease, there was marked general prostration, and the patient continued feeble for months afterwards. The whole course of the case seemed to indicate that the poison carried by the fly had produced the local inflammation and also some general poisoning. 2. A man aged twenty, in whom acute swelling of the right eyelid and conjunctiva came on two days after a fly had got into his eye. The inflammation soon became unmistakably diphtherial and led to complete destruction of the cornea and very serious general symptoms. It is not certain that the diphtherial poison was introduced by the fly, yet the rapidity with which the symptoms followed the accident was thought to be at least suggestive.

Dr. BERRY described shortly a group of cases under the title of Hyperplastic Subconjunctivitis. In three cases there was to be felt a hard swelling occupying the tissues below the conjunctival fold of the lower lid. This was in some associated with the irritation and discomfort common to chronic conjunctivitis. It seemed probable, from clinical experience, that the subconjunctival infiltration originated at a time when the conjunctiva was inflamed, and, for some reason, was not altogether absorbed afterwards. But an independent hyperplasia might arise in this more or less organised deposit, causing it to swell to a greater or less extent, and to be accompanied by symptoms of irritation. In fact, in pronounced cases, the conjunctivitis was very slight, although there might be chemosis and swelling of the pre-auricular glands.

Dr. BERRY also gave an account of some of the facts elicited during experiments on Intra-ocular Injection of Antiseptic Solutions in Rabbits, undertaken by his assistant, Dr. Chassaud, with the object of ascertaining the effect of different solutions injected into the vitreous. In some cases, before injecting the antiseptic, the vitreous was inoculated with fresh septic pus. The only substance injected after the inoculation which seemed capable of preventing purulent hyalitis was chlorine water. At the same time this injection was much better tolerated by the retina and vitreous than any other strong antiseptic solution. In two cases of purulent hyalitis in men chlorine water injected into the vitreous led to immediate improvement, and the eyes were saved although sight had been lost before the treatment was adopted.

Dr. BERRY likewise recorded a case of Intra-ocular Absorption of Iodoform in which, after extraction of senile cataract, he had applied iodoform freely to the wound. On examining the eye next day the anterior chamber was found to be filled to the extent of apparently two-fifths of its capacity with iodoform and the rest of the aqueous to be turbid. At some parts caked portions of iodoform could be seen plastered as it were upon the iris. The iodoform was gradually absorbed without causing any great irritation. In a fortnight no trace of it could be seen, and the result of the operation was good.

Mr. CATGER mentioned a case seen by himself at Moorfields Hospital, which, he considered, was analogous to the cases described in Dr. Berry's first communication. The patient, a stableman, received a blow in the eye from a worm derived

from the intestine of a horse. Very marked chemosis of the conjunctiva followed, but gradually subsided. Mr. Caiger thought the condition might have been due to the introduction of some poisonous material contained in the excreta of the horse.—Mr. LAWFORD expressed the opinion that the condition described by Dr. Berry was recognised as hyperplastic conjunctivitis, and asked if he had met with it more frequently in old or young patients, or in connexion with any particular dyscrasia, and what plan of treatment he had found most suitable.—Dr. HILL GRIFFITH (Manchester) suggested trichloride of iodine as being a very suitable substance for intra-ocular injection. It readily broke up into chlorine and iodine and was said to be non-irritating.—Mr. HARTRIDGE stated that cases not infrequently occurred in which the injection of germicidal solutions into the eye was indicated. If it could be shown that such a measure might be safely adopted, many eyes which now had to be removed might be rescued.—Mr. DOYNE mentioned a case in which he had injected boric acid solution into the anterior chamber, washing out on two occasions complete casts of purulent matter. The eye gradually recovered.—Dr. BERRY, in reply, said that hyperplastic subconjunctivitis usually occurred in adults, and was very chronic. He had not found its course materially affected by treatment. Improvement in one case had followed the exhibition of salicin administered under the impression that the disease was of a rheumatic nature. With regard to intra-ocular injections, Dr. Berry thought it probable that a distinct advance in ocular therapeutics might be made. He believed that a comparison could scarcely be made between injections into the anterior chamber and into the vitreous. The anterior chamber he had himself frequently irrigated with solutions of perchloride of mercury, but with the usual opacity of the cornea as a consequence, though this was of less intensity in children than in adults.

The following card specimens were shown:—

Mr. STANFORD MORTON: Cyst of Iris.

Mr. JOHN GRIFFITH: Rupture of Sclera without marked Defect of Sight.

Mr. HARTRIDGE: (1) Multiple Ruptures of Choroid; (2) Case of Aniridia.

Mr. WORK DODD: Case of Aniridia.

## OTHER METROPOLITAN MEDICAL SOCIETIES.

HARVEIAN SOCIETY OF LONDON.—A meeting of this Society was held on Oct. 20th, Dr. W. B. Cheadle, President, in the chair.—Mr. J. JACKSON CLARKE showed specimens from the St. Mary's Hospital collection illustrating Purulent Peritonitis from menstrual ovarian hæmorrhage, from puerperal septic infection, and from perforation of the vermiform appendix. The latter specimen was interesting from a curious exaggeration of the normal sacculatation of the colon due to long-standing constipation. Mr. Clarke also showed specimens illustrating rupture in tubal pregnancy and remarked on the certainty with which chorionic villi could be recognised in sections and in teased clot.—Mr. LAWSON TAIT read a paper on Peritonitis. At the outset he stated that the time at his disposal would only allow of his dealing with traumatic peritonitis or that following upon operations on the abdominal cavity. With regard to the pathology of inflammation Mr. Lawson Tait confessed that he was "quite at sea." In peritonitis the germ theory was useless. The cause of death in peritonitis was the disturbance of the ebb and flow of the serum stream of the peritoneum and the disturbance of the function of the liver. As to treatment, the great thing to do was to prevent peritonitis; as a rule, one had no chance of curing it. Years ago he gave up the use of opium on the grounds that it masks the patient's condition and diminishes the vermicular action of the bowels. He had banished ice from the treatment of thirst consequent upon opening the abdomen; the best thing to use was warm water. Of late years he had even diminished the amount of fluid to the vanishing point. If sickness occurred on the third or fourth day all food, including water, was stopped for twelve hours. Should the patient be unable to pass flatus for twenty-four hours after the operation, the nurse must, on her own responsibility, proceed to administer a turpentine enema. If this did not succeed, a mild saline purgative was given.

Mr. ALBAN DORAN agreed with Mr. Tait in regard to the question of keeping the patient's stomach empty for some time after operation. On the other hand, nutrient enemata should be given, except in young or very robust patients. Mr. J. JACKSON CLARKE protested against the pathological opinions Mr. Tait had expressed. Mr. Tait had said that in several conditions he had tried for the first time new operative measures. Mr. MALCOLM said that Mr. Tait had suggested an ebb and flow in the peritoneal cavity connected with the excessive secretion of bile in peritonitis. Mr. Malcolm maintained that the symptoms described occur without the existence of any peritonitis at all. He drew attention to the fact that a traumatic inflammation reaches its culminating point in about three days. Mr. Malcolm argued that it is an obstruction or a paralysis of the bowels that causes the distension and other symptoms, and that any peritonitis found after death was secondary to this complication. Dr. HEYWOOD SMITH said the profession owed a debt of gratitude to Mr. Lawson Tait for having done so much to promote the administration of purgatives in the preliminary stage of peritonitis. Dr. BOXALL would speak to one only of the many debatable points raised in Mr. Tait's interesting paper. His experience at the General Lying-in Hospital as regards scarlet fever was strictly analogous to that of Mr. Tait in operation cases. For the last thirteen years the service of the hospital had been conducted upon Listerian principles.

HUNTERIAN SOCIETY.—A meeting was held on Wednesday, Nov. 9th (clinical evening), Mr. R. G. Tatham, Vice-President, in the chair.—Dr. G. E. HERMAN showed Champelier de Ribes' Bag for Dilating the Cervix Uteri, lately invented for this purpose.—Mr. J. S. E. COTMAN brought forward a man aged about thirty-five, who had a carbuncle behind his left knee last year, and after this healed ulceration commenced and gradually spread, healing in the centre, with scolloped undermined edges. Mr. R. G. TATHAM and Mr. J. POLAND considered it syphilitic in nature.—Dr. T. MARSHALL showed a man of about forty-five years of age who had been troubled by perspiration on the right side of his face on excitement for about nine years since a severe attack of typhoid fever. Dr. HINGSTON FOX referred to cases of sweating of limited portions of the face in children of an unstable nervous disposition—e.g., of one side of the nose, and parts of one cheek and brow. He had shown a case of hyperidrosis of a limited area on one forearm in a hysterical girl. Mr. COTMAN had exhibited last year a case of sweating of one half of the face following parotid suppuration, in which he thought there had been some blending of the nerve fibres of the chorda tympani and auriculo-temporal nerves.—Dr. A. T. DAVIES exhibited a case of Graves' Disease in a woman aged forty-three years; the symptoms—palpitation, proptosis, goitre, tremor—were all well marked, and the interest lay in its long duration, twenty-three years. Mr. DENTON CARDEW had observed deaths from diabetes and from the exhausting diarrhoea which occurred in some severe cases. When cured, the thickening of the thyroid and the eye conditions were generally permanent. The pulse rate became much exaggerated on excitement.—Dr. GLOVER LYON showed a woman aged about thirty-five years, with extensive persistent hyperæmia and hypertrophy of the left shoulder and almost entire upper extremity. The skin was red, the colour disappearing on pressure, the bones and muscles enlarged (patient was not "left-handed," though this upper extremity was the stronger). The surface was warmer than on the other side, but often felt more chilly to the patient. The condition was congenital.—At a meeting on Oct. 26th, Mr. F. Gordon Brown, President, in the chair, a discussion on Phtthisis in Relation to Life Assurance was introduced by a paper by Dr. GLOVER LYON, based on an inquiry by himself and Mr. Manly, the actuary of the Mutual Life Office, into the mortality experience of that office. The statistics obtained were explained in some detail and compared with the returns of mortality from phtthisis by the Registrar-General, but it was admitted that the figures were not large enough to base conclusions upon. Dr. J. E. POLLOCK referred to the Brompton Hospital statistics, indicating that 38 per cent. of phtthisical patients showed the taint of heredity. Parental heredity was the great element, but it went back also to grandparents. Two things modified heredity, age and physical condition, and this was the more important element. We declined a man of delicate build, shallow-chested, shabby and flabby tissued and taking no exercise. Dr. SYMES THOMPSON believed that in cases of well-defined lung disease we could make a more

certain prognosis than in small manifestations of imperfect health. Statistics of his own office had shown that minor defects, such as leanness, stoutness, plethora and corpulence, were bad in their results. Dr. W. SEDGWICK SAUNDERS said his idea of the duty of a medical examiner was to select good lives, and not to attempt to pass all lives. He quite agreed as to the preponderating importance of personal physique.

THE ISLINGTON MEDICAL SOCIETY.—At a recent meeting of this Society Mr. C. B. LOCKWOOD read a paper on the Radical Cure of Hernia, with a selection of suitable cases and the results of the operation. He said no operation ought to be called a radical cure unless it enabled the patient to dispense with a truss. By open methods of operating and asepsis this could now be done in suitable cases. Asepsis was attained by scrupulous care in the preparation of the patient and of the materials used in the operation, and also by simple and correct operating. The operations for the cure of inguinal and femoral hernia were described. It was most important to avoid interference with the scrotum, and after obliteration of the sac, the inguinal canal in one case, and the femoral canal in the other, were secured with a series of buried silk sutures. These were deeply introduced with powerful blunt-pointed needles. The operation for the cure of femoral hernia was particularly favourable, and, as there was no spermatic cord to embarrass the operator, it was easier to accomplish than that for the cure of inguinal hernia. The operation of radical cure was called for after kelotomy; it prevented immediate recurrence of the hernia, subsequent relapse of the hernia, protrusion of the sac, sloughing of the sac, and suppuration in the sac. It was also expedient in irreducible hernia of small dimensions, especially in cases of femoral epiplocele; in cases in which a truss was inefficient in schoolboys, and lastly in those who were candidates for the army, navy, or other services. For the obtaining of good results a proper selection of cases was imperative. The extremes of life were unfavourable. Amongst unfavourable conditions were those in which the hernia had been neglected, leading to the formation of huge hernial apertures. Finally, the recognition of the fact that in many cases of acquired hernia the local condition was only part of the disease was of the highest importance. There is a class of cases in which the tissues are generally deteriorated, with prolapse of the mesentery, of the colons, transverse mesocolon and kidneys. The usual routine of an operation was described. The dressing was removed on the eighth or tenth day, the patient remained recumbent three weeks, took carriage exercise for another three, and did not ride or violently exert himself until three months after the operation.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this Society was held on November 4th, Mr. F. Swinford Edwards, F.R.C.S., in the chair.—Mr. R. F. BENHAM showed a large Ovarian Cyst to which the vermiform appendix was adherent. In operating hæmorrhage from the appendix was so severe as to necessitate its ligation and removal.—Dr. CROMBIE exhibited the Heart from a case of Ulcerative Endocarditis, of which he read the notes. The patient was a young man and an athlete and the symptoms came on after a sprint. The temperature was never high, neither was pericardial friction audible at any time.—Dr. THUDICHUM read a paper on Gall-stones, their Origin, Nature and Treatment of the Diseases to which they give rise. The author referred to his previous researches by which he had proved that gall-stones were originally caused by a catarrh of the mucous epithelium and glands of the bile ducts. This led to the formation of casts of the ducts, and around them, after they had been shed, the gall-stone matter was deposited. During the catarrh bacteria entered the ducts from the duodenum and caused decomposition of the bile. Foreign bodies were rarely the cause of gall-stones. The difference between human bile and that derived from animals was next referred to. The statement that the bile contained lecithin was directly disproved. He next showed that the products of decomposition of ox bile and of human bile corresponded with the ingredients of their relative gall-stones. A rational medical treatment of gall-stones could only be based upon a right appreciation of the functions of the liver and bile. The steps of the operation of cholecystotomy were described, as also the method of crushing the calculi in the bladder or ducts; and where this was impossible, it was recommended to cut them out, closing the ducts by suture. In the treatment of colic he advocated the use of morphia

subcutaneously, of large quantities of very dilute lemonade, and of chloroform anaesthesia when collapse threatened. The paper was illustrated by drawings and specimens and was followed by a discussion.—Dr. HENRY SUTHERLAND read a paper on the Prevention of Suicide in the Insane, a full report of which will appear in our columns. In the discussion which followed, in which the President, Dr. Alexander, Mr. Atkinson and Mr. Lloyd took part, the treatment in private of cases on the borderland of insanity, where there was a suicidal tendency, was dealt with. In his reply, Dr. Sutherland advocated the most careful and ample supervision, and where it was feasible (in non-certifiable cases) their admission as voluntary patients into asylums.

## Reviews and Notices of Books.

*Elements of Human Physiology.* By ERNEST H. STARLING, M.D.Lond., Joint Lecturer on Physiology at Guy's Hospital. Pages 464 with 94 woodcuts. London: J. & A. Churchill. 1892.

IN a work of this kind it is not so much the fulness and completeness of the exposition given that have to be considered, but rather the clearness with which the facts are presented to the student and the judgment with which those facts are selected. It is manifest that it is impossible to compress into the compass of less than 500 small pages the whole of the facts that are given in such a work, for example, as that of Landois, but, fortunately, it is only the principles which are of real importance and which the student should really be required to know. In these respects we think Dr. Starling has done his work well, and that the student who has mastered his book in his first or second year will have acquired enough information to enable him to take up with advantage one of the larger treatises. A long and well-written section is devoted to the vascular mechanism, in which the cause and the mode of estimating blood pressure are given together with the changes occurring in the heart at each contraction. The author remarks correctly that, in the normal condition when the pericardium is intact, the apex remains almost stationary during contraction; but he goes on to say "that this is owing to the fact that the pericardium is fixed externally, and the apex could not rise without causing a vacuum between it and the pericardium." Is not the stationary position of the apex due to the combination of the rising of the apex consequent upon contraction of the muscular fibres of the ventricles being compensated by the recoil of the whole heart consequent upon the elasticity of the great vessels which react to the sudden pressure exerted by the issuing blood?

The facts relating to the nervous system seem to us remarkably well written—as, for example, the section on the Inhibitory and Accelerator Nerves of the Heart, and that on the Vaso-motor Nerves—difficult points to give well. We notice, however, that an important diagram, Fig. 49, has no explanation of the lettering, either at the foot or in the text, and though an advanced student may recognise its meaning it would be entirely beyond the understanding of the beginner for whose instruction the work is designed.

Throughout the work Dr. Starling omits all reference to histology, which indeed it is impossible to enter upon in a work of this size with the least advantage to the student; nor is it desirable when there are already two such excellent manuals in the field as those of Klein and Schüfer. Reproduction is dismissed in less than a dozen pages. In a short appendix a description is supplied of some of the instruments more commonly used in physiological research. Finally there is a good index. The work as a whole fulfils its intended purpose, and can be safely used by the student as a reliable guide.

*A Short Manual of Inorganic Chemistry.* By A. DUPRÉ, Ph.D., F.R.S., F.C.S., &c., and H. WILSON HAKE, Ph.D., F.C.S., F.I.C. Second Edition, Revised. London: Charles Griffin and Co. (Limited). 1892.

THE first edition of this work was favourably noticed in THE LANCET some few years back, and we are pleased to see that our opinion of its merits has been confirmed by the fact of a demand having since arisen for the issue of a second edition. We heartily agree with the line of treatment which the authors have adopted. They believe—and they have had considerable teaching experience—that general principles should precede what may be termed “descriptive chemistry.” In other words, the student should be presented with the axioms of chemistry before he is brought to consider the practical portion of the science. He thus gains a sound acquaintance with theory, a knowledge of which may be acquired without any previous knowledge of chemistry whatever, which enables him to carry on his practical work more systematically and intelligently and with greater profit than before. The book is written in a clear and easy style, the facts are well arranged, and the few blemishes which we had occasion to point out in a previous notice have been effaced. In the article on Carbonic Oxide we should like to have seen some reference to the peculiar and interesting action of the gas upon nickel and iron recently described by Mond and others. All other facts, however, are in accordance with modern requirements; as examples, the preparation of fluorine and phosphorus trioxide may be cited. A feature of the work is the introduction of a short paragraph here and there to describe the physiological action of the more important elements and compounds. We know of no better text-book on the subject of inorganic chemistry than the one before us, and our hope is that the authors may at some future time be prompted to write a second volume in similar style, dealing with the organic section of the science, so that the whole range of the subject may be brought within the compass of one text-book—a want that is still felt by medical students and others.

*Napheys' Modern Therapeutics.* Vol. I. General Medicine and Diseases of Children. Ninth Edition, Revised and Enlarged. By ALLEN J. SMITH, M.D., and J. AUBREY DAVIS, M.D. London: Baillière, Tindall and Cox. 1892.

NAPHEYS' Therapeutics is a work of established reputation, which will be increased by the present handsome volume. The aim of the work was indicated in an earlier edition very clearly; it was intended to acquaint the reader with the exact treatment of each disease by living clinical teachers and careful practitioners of several countries. This information, as the book has grown, has been drawn from various sources: the periodical literature has been consulted, notes of clinical lectures have been referred to, and sometimes inquiries have been addressed to eminent physicians as to their most successful methods of treating various diseases, and their replies have been incorporated. Such a work needs constant revision. Space has to be found for much that is new by the removal of certain statements that have become antiquated, and hence considerable care must be expended in the process of pruning and lopping. The editors have—wisely, we think—returned to the plan of having only two volumes in place of four, reserving the first (which is before us) for General Medicine and Diseases of Children, while the second will comprise General Surgical Therapeutics and Gynecology. In the section upon General Medicine the physiological systems form the basis of arrangement, a separate chapter being devoted to Toxic Diseases. Very rarely a few brief clinical features are mentioned when they have an important bearing upon the etiology and treatment; as a rule, the excerpts comprise only an account of the treatment adopted and the method of its employment, each author being

given full credit and responsibility for his statements, and each subject being presented from many, even conflicting, points of view. The advantage of this is obvious. The work is one which may be consulted frequently and from which many valuable and suggestive hints may be obtained. For the busy practitioner the frequent introduction of formulæ will be found attractive, but, as the writers are culled from all parts, it may be well to bear in mind that many prescriptions are of American origin. Congratulations are due to the editors for the industry which has left but few recent statements of importance unnoticed, and to the publishers for the very attractive and serviceable way in which the volume has been produced.

*Temperament, Disease and Health.* By FRENCH ENSOR CHADWICK, Commander, U.S.N. New York and London: G. P. Putnam's Sons. 1892.

IN a little volume of eighty-five pages of rather large type, with an amplitude of margin that would delight Mr. Ruskin, Commander Chadwick essays the solution of the difficult and obscure problems arising out of the bearing of temperament and diathesis upon health and disease. He aims especially at putting forward two ideas—(1) that there is associated with temperament a specific rate of change (tissue change is apparently meant); (2) that the failure to keep up that rate—or, in other words, a failure of elimination to keep pace with accession of material—is the primal cause of organic disease. This may be true regarding such diseases as Bright's disease or rheumatism, but what has defective elimination to do with, say, bronchitis or meningitis, or tuberculosis or cancer? Vague generalisations are the greatest of snares. The author inclines to the view attributed to Dr. Paul Gibier, that there are three temperaments—viz., the alkaline, the acid and the neutral. Capacity for going a long time without food and of sleeping at will is, we are informed, “always associated with gray eyes or gray eyes shot with brown.” We do not know what are Commander Chadwick's scientific or medical qualifications for dealing with some of the most difficult questions to which the human mind can address itself, but, with all respect, we feel it difficult to take his book seriously. *No sutor*—; the proverb if old is generally applicable.

#### OUR LIBRARY TABLE.

*The Art of Feeding the Invalid.* A Series of Chapters on the Nature of certain Prevalent Diseases and Maladies, together with carefully selected Recipes for the Preparation of Food for Invalids. By a MEDICAL PRACTITIONER and a LADY PROFESSOR OF COOKERY. London: The Scientific Press, Limited. 1892.—Every practitioner is aware of the essential importance of a suitable and carefully selected dietary in certain cases of disease and of its importance in most of them, as well as of the difficulty of the task of adjusting the diet, in point of variety particularly, from day to day to the fastidious tastes and requirements of invalids in all cases. Miss Nightingale was quite right when she said that a number of sick people are annually starved in the midst of plenty from want of attention to the ways which alone make it possible for them to take food. There is no doubt, too, that patients in private houses fare worse in this respect than patients in hospitals on account of the greater knowledge and experience as well as supervision which are exercised in the latter—in cases of serious disease especially. This book deals with certain prevalent diseases in different chapters, lays down general statements as to their several natures and the principles to be followed in providing a daily diet, and refers to a series of recipes, so that a patient can be provided throughout his illness and convalescence with a system of diet suited to his condition. It points out “what to eat, drink and avoid,” a main object of the authors being to secure for the invalid

as great a variety of well-prepared food as possible. Its design is consequently excellent, and we think it has been successfully carried out, containing, as the work does, information not hitherto published in such a form. It is scarcely necessary to remark on the usefulness of information of this kind to matrons of institutions, sisters and nurses and heads of households, and to all concerned with the care of sick and delicate people.

*Golden Rules of Surgical Practice for the Use of Dressers.* By E. HURBY FENWICK, F.R.C.S. Eng., Surgeon to and Lecturer on Clinical Surgery at the London Hospital &c. Third Edition. Bristol: John Wright and Co. London: Simpkin, Marshall and Co. 1892.—The usefulness of this little book, originally designed for hospital dressers, is not likely to be confined to them. It is sound, short and serviceable; and these merits seem to have been recognised, for this is the third edition of "Golden Rules." It is a good shilling's worth.

*Elementary Physiography, being a Description of the Laws and Wonders of Nature.* By RICHARD A. GREGORY, Honours Medalist in Physiography, author of "Physical and Astronomical Geography" &c., Fellow of the Royal Astronomical Society &c. London: Joseph Hughes and Co. 1892.—We have been much pleased with this book, which is largely illustrated, many of the illustrations being original. The information is well put together and lucidly rendered, and we have no hesitation in recommending it as a very good one of its kind.

*Dental Anatomy and Physiology.* By JAMES F. RYMER, M.R.C.S., L.D.S. Eng. London: C. Ash and Sons. 1892.—This little work belongs to that numerous class of note-books designed for students preparing for examinations, and whatever their real value there must be a demand for them, as so many, as in this case, reach a second edition. It is practically a digest of Tomes' Manual in Dental Anatomy and very little matter from other sources is added. It would doubtless have been of greater use had it been fuller, and this defect the author himself has probably felt since he has interleaved it so that the student may add his own notes. We think it a mistake to have omitted a description of the development of the jaws, which would have added only a few pages to this small note-book.

"*The Best Thing to do*": *First Aid in Simple Ailments and Accidents.* By C. T. S. THOMPSON. London: Record Press.—This little work, which will no doubt prove of some service to tourists and travellers, is by no means intended to supersede medical advice when available. The first part comprises eight chapters of valuable information as to the best health resorts both at home and abroad, with suggestions to those about to undertake a sea voyage. The second part is devoted to the treatment of accidents, and gives a fairly selected list of simple remedies useful in emergencies. The last chapter consists of a register of British medical practitioners resident abroad, followed by some blank pages for memoranda.

## THE PÆDIATRIC CONGRESS IN NAPLES.

So important in Italy is the hygiene of childhood that it has almost risen to the rank of a State question, to be ventilated at every possible season until the Legislature makes it a feature in its internal programme. The largely attended gathering recently held at Naples is indeed but a rehearsal of a yet more influential one, to meet under the Sezione Pediatrica in the great International Congress of September, 1893. In no country in Europe is there a louder call for reform in the treatment of infancy than in Italy. The poverty of the inhabitants in such provinces as Calabria has encouraged a traffic in their children—well called by the *Opinione* a "white

slavery"—in which parents sell their offspring to itinerant organ-grinders for service as "performing children" in the streets of Vienna, Berlin, Paris, London and New York. Nor is the lot of those other children whose less attractive looks or inferior precocity saves them from such a career a much more happy one. Neglect, even abandonment, at best a meagre upbringing and a premature enforcement of hard work are the portion of so many of the boys and girls of pauperised Italy, that the results, conspicuous in heavy mortality, and, among the survivors, in vice, disease and even crime, have compelled the more philanthropic of the people to interpose for the protection of the rising generation. The public press has warmly taken the matter up, and the *Tribuna*—an advanced Liberal organ of the widest circulation throughout the peninsula—has for some time organised a crusade on behalf of its little compatriots. At the Naples Congress the first paper on the *agenda* was thus entitled, "Sulla Istituzione Urgente in Italia di una Grande Società Protettrice della prima Infanzia," and the names of its conjoint authors—Professor Blasi of Rome and Professor V. Massini of Genova—attest the importance the subject has assumed even in seats of learning. In their preamble, Professor Blasi and Massini say: "Our laws as they stand to-day, our administrative machinery, our institutions afford small guarantee for the health and life of millions of children requiring tutelage and upbringing. For us who boast of our civilisation, what remains but to organise private relief, embodying all the active philanthropy of the country? Should the coöperation of every social class and calling be secured for this end, and, moreover, should the official authorities lend their support, the practical effects would be as salutary as they are loudly called for. .... We are not dealing with pædiatry only; ours is a cause profoundly humanitarian, which the whole community is interested in promoting." The paper which followed and which will shortly appear in a permanent form, gave statistics of the most eloquent character on behalf of Italian children. In France, in Belgium and in England, out of a million of the very young, 280,000 die before their tenth year; while, in Italy, the corresponding deaths reach the terrible figure of 420,000, of whom a vast proportion might have been saved by ordinary surveillance and care. The solicitude shown by France and England for their poorer children evoked the warm praise of Professors Blasi and Massini. A series of practical suggestions followed, many of them inspired by British initiative, and requiring no further notice on our part than the observation that they seem judiciously fitted to meet the Italian problem where legal difficulties and Church jealousies intervene to hamper so much that is indicated for the surveillance and development of youth. An animated discussion ensued, in reply to which Professor Blasi vindicated his positions at length, and, by the unanimous vote of the Congress, carried the subjoined propositions: (1) To promote and popularise the principles and practice of infant hygiene; (2) to safeguard hired nursing by the domiciliation of the nurses and the superintendence of the weaned when at a distance from their own families; (3) to encourage, diffuse and improve the infantile sanitary institutes; (4) to watch and—on occasion—to assist with well-timed relief cases of infants threatened by extreme poverty in the matter of health and life; (5) to prevent such maltreatment of children as may endanger their health. These provisions will be embodied in a statute afterwards to be discussed, and—when approved—to be brought before the Government with a view to legislation. The subsequent proceedings of the Congress were of an interest much less dramatic than that of the foregoing paper, but still well worth the notice of the profession and included an able memoir by Professor De Bonis on the "Relations between Scrofula and Tuberculosis in the Diseases of Children; a vindication of "Creasote in Infantile Tuberculosis," by Dr. Guida, in which he drew largely on his clinical experience; a paper on "Hereditary Syphilis in Children," by Dr. Antonio Carini of Palermo, which elicited much divergence of opinion; and a memoir by Professor Fasano on "Scarlatinal Diphtheritis." These, with a full report of the discussions they evoked, will appear in the official "Transactions," a volume which must have considerable attractions for the profession at large.

THE Westminster Hospital Students' Dinner took place at the Criterion on Tuesday. Mr. James Black, F.R.C.S., occupied the chair. The dinner was followed by a concert.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 19, 1892.

THE work of the Medical Council is theoretically divided into two parts or kinds—the one having reference to questions of medical education and the other to questions of medical conduct. By a division equally theoretical the summer session has been assigned chiefly to the first set of questions and the autumn meeting to the consideration of the second. It has never been found possible in practice to restrict the attention of the Council at one sitting to one set of questions. At the last meeting in May the time of the Council was occupied mainly with questions of professional conduct. One question—and almost only one—bearing on medical education was discussed or, rather, raised—viz., the Preliminary Examination of the Apothecaries' Society. The Apothecaries' Society is almost the only one of the medical licensing bodies which continues to hold its own preliminary examination. The other licensing bodies have agreed to leave such examinations to the educational bodies of the country as the College of Preceptors, the universities or colleges, or, as in Scotland, to the Educational Institute of Scotland or the Scotch Education Department. But the Society is loth to abandon its preliminary examination, which, indeed, is rather popular. Popularity is perhaps not the best test of an examination. Be this as it may, the Society examines between 700 and 800 candidates a year. This, of course, is many more than the number of those who proceed to its professional examinations. According to the last minutes of the Medical Council it examined in 1891 780 candidates, of whom 631 were successful. This is a large proportion of success. The Council has been made sensitive on this subject by a reminder from the War Office that candidates for army and navy appointments are often found to be defective in general education, and by an intimation that such defects will be treated as a ground of rejection. It has not yet been shown what particular examinations, if any, are responsible for admitting into the profession those who are so defective. Meantime the Medical Council adheres to its principle that the medical examining bodies should divest themselves of all responsibility for examinations in preliminary education. It may be expected that this question between the Society and the Council will be warmly debated. It is not pretended that the Council can deprive the Society of its preliminary examination, but it can withhold its recommendation of the examination. It is certainly desirable that the preliminary education of those who propose to enter the profession should be tested more severely than ever if the profession is to hold its own, and if unfit persons are to be excluded. This subject may be expected to again occupy the attention of the Council. As to the question of medical education proper, the most important subject which is likely to engage the attention of the Council is that of the new regulations with regard to the fifth year in the medical curriculum. It is not certain that the material for a judgment in the shape of the regulations of the various bodies will be before the Council at the approaching meeting; but the subject cannot

be long postponed, and is one of immense importance. The addition of a fifth year to the period of education is essentially the act of the Medical Council, and on this body devolves the responsibility of seeing that it is well used. But whatever may be the pressure of educational questions at the meeting, it is evident that the Council will have many serious matters to deal with of an ethical or professional character. It is only necessary to watch the newspapers and their reports of inquests and trials to see that questions affecting the propriety of medical conduct are being constantly referred to the Medical Council, and that unless some way can be devised of dealing primarily with such instances by the bodies from whom the inculcated practitioners hold their diplomas, more and more of the valuable time of the Council must be occupied in dealing with them. This very question, however, of the primary responsibility of the individual bodies for the good behaviour of those whom they authorise to practise is itself likely to arise in the Council. Our readers may remember that at the last meeting of the Council Sir JOHN SIMON spoke very strongly on this subject, and on the last day of the session wished to propose a motion asserting the duty of the bodies to deal with their own members, leaving to the Council only the duty of removing from the Register names representing qualifications withdrawn by the bodies which had given them. He was not allowed to do so by the Council at the last moment of the session. It is to be hoped that nothing will prevent Sir JOHN SIMON from bringing forward his motion at the meeting to be held next week. The matter is urgent, and no member of the Council can speak on it with more authority and weight than Sir JOHN SIMON, who knows, perhaps, more of the Medical Acts and of that which was in the minds of their framers than any other member of the Council, past or present. But apart from all such abstract questions it is obvious that some very difficult and grave matters will come before the Council, which it will have to dispose of with more than usual care, and it will have to consider whether its present rules and action are sufficient to check growing evils, and, we may add, growing scandals. A new question will also be brought prominently under its notice, as the readers of THE LANCET will have seen—viz., the right of medical men to enter into contracts with associations of non-medical persons for supplying medical services on low terms, the profits arising accruing mainly to the association, and taking the shape of dividends or investments. It is not for us to anticipate the discussion of this question or the judgment of the Council on it. We have said enough to show that the proceedings of the Council will be of exceptional interest to the profession and the public.

A DISCUSSION on the value of abdominal section in certain cases of pelvic peritonitis has occupied the attention of the Obstetrical Society of London at its last two meetings. No subject could be found better deserving the Society's careful consideration, for not only do cases in which there is pelvic peritonitis form a large proportion of gynecological cases as a whole, but a large number of them come, in the first instance at least, under the care of the general practitioner. The question considered in Dr. CULLINGWORTH'S paper, on which the discussion arose, was as to whether abdominal section is or is not frequently called for in this

group of cases. Much difference of opinion was shown on this point in the course of the discussion, some taking the view that abdominal section is rarely required in these cases, while others, and among them Dr. CULLINGWORTH himself, supported the opposite opinion. We think the different opinions expressed may perhaps not be quite so irreconcilable as they at first sight appear to be. Some of the diversity may probably be accounted for by want of a more precise definition as to the kind of cases for which abdominal section was recommended. The title of the paper defined these as "Certain Cases of Pelvic Peritonitis." Now, while pelvic peritonitis, as in many typical cases following labour, may be *the* disease present, it may also exist as a secondary and relatively unimportant factor in various conditions; for example, it is a common complication in cases of extra-uterine pregnancy, ovarian tumours, dilated Fallopian tubes, fibroid tumours of the uterus, cancer of the uterus, and pelvic cellulitis. All agree as to the propriety of abdominal section in cases of ovarian tumour; and probably, on the other hand, in the case of fibroid tumours of the uterus, Dr. CULLINGWORTH would himself agree that the operation is rarely necessary. Yet in both instances there is often pelvic peritonitis present as a complication, and in that sense they would be included under the comprehensive title "Certain Cases of Pelvic Peritonitis." We may probably, however, assume that the opinions expressed for and against abdominal section refer more particularly to the question of operation for what is known as "chronic inflammation of the uterine appendages." By this we understand a condition of things where the fimbriated end of the Fallopian tube is closed by adhesive peritonitis, the tube being usually thickened and often dilated to a various extent, and containing either clear fluid, pus, or blood, thus constituting a hydro-, pyo-, or hæmato-salpinx, as the case may be. There are usually more or less extensive adhesions between the dilated tube, the ovary, the uterus and the adjacent parts. Tubes so dilated may form tumours the size of a hen's egg, or often very much larger. The experience of those who have frequently to open the abdomen, and observations in the post-mortem room at some of our general hospitals, go to prove that the condition of the Fallopian tubes just described is a far from uncommon one. In endeavouring to come to some practical conclusion as to the propriety of abdominal section where this condition exists, we think it will be most useful to keep as closely as possible to facts, which we may frankly say appear to us to be at present too meagre to justify the adoption of any general rule comparable to that long since arrived at with regard to the treatment of cases of ovarian tumour. The facts in our possession, then, may be stated as follows: 1. Dilatation of the Fallopian tubes to a greater or less extent is a by no means rare condition. 2. Many of the patients in whom this condition exists suffer from some of the following symptoms: pain in the lower abdomen; backache; disturbances of the menstrual function, the catamenia being excessive, scanty, or attended by severe pain; dyspareunia; feverish attacks. 3. In a certain proportion of these cases the symptoms disappear and the disease passes into a state of quiescence under palliative treatment. 4. In a certain number of cases, after temporary improvement, the symptoms recur and the patients become

chronic invalids. 5. The presence of a pyo-salpinx is a distinct danger to life, but we cannot at present diagnose between a hydro-salpinx and a pyo-salpinx with any certainty. A distinct history of gonorrhœa and the occurrence of feverish attacks would be to some extent in favour of pyo-salpinx. 6. While a certain number of cases are permanently relieved by removal of the diseased organs, it is well known that some are not relieved by the operation, and that some are even worse than beforehand. 7. It has been clearly established that there are some cases where anything at all approaching a complete removal of the diseased organs is utterly impossible; since, even in the post-mortem room, in some cases, it is a matter of the utmost difficulty to dissect out the dilated tubes in an anatomically complete condition without serious injury to vital organs, so intimate is the fusion of the diseased tubes with adjacent parts. 8. In the majority of cases it is possible to remove the diseased organs completely, though the operation is not rarely attended by considerable difficulty.

We think the points we have recapitulated suffice to show, at all events, that the subject is one of great difficulty and complexity, and that the time has not yet come when it is possible to formulate any general rule for the management of these cases. Each case must be judged on its own merits when the question of operation is under consideration. Careful examination under anæsthesia is of great value in giving precision to our knowledge of the exact physical condition of the pelvic organs, and so enabling us the better to judge if the diseased parts can probably be removed completely, and also to some extent of the severity, or otherwise, of the procedures necessary for the purpose. The fullest information should be given to the patient as to the probable outlook in the special circumstances of her particular case; not forgetting that while the mortality of dilated Fallopian tubes is very small, that of the operation for their removal is not insignificant, and that the more extensive the disease, the greater is the risk.

At the present season, when the question of winter quarters is engaging the attention of many practitioners and patients, a brief survey of the subject may prove of interest and value to our readers. The classes of persons who go abroad for the winter may be enumerated as follows: Those who simply wish to avoid the cold, damp and depressing influences of the British climate from November to April; sufferers from anæmia, debility, overwork, impaired convalescence from acute disease, or surgical operations; gouty and rheumatic and renal cases; neurotic cases, including both functional and organic nervous disease; pulmonary cases, including sufferers from phthisis, bronchitis, asthma, unresolved pneumonia and chronic pleurisy. The above list might be easily enlarged, but it includes the principal classes of invalids who may be expected to benefit by a well-planned residence abroad. The needs of the different classes necessarily vary within wide limits and will be considered in the course of our observations. In the present article we shall confine ourselves to a short survey of the climatic and meteorological features of the chief sanatoria available for those who have decided to winter abroad. Before proceeding further, however, we must not ignore the fact

that within the limits of the British islands there are many winter resorts of great value in certain cases. Hastings, Ventnor, Bournemouth, Torquay, Falmouth, Ilfracombe, Queenstown and Glengariff—to name a few out of many—possess considerable merits as winter sanatoria. They have a fair degree of warmth and mildness, picturesque scenery, excellent accommodation, and are accessible. But the moment any exact comparison between these English and Irish resorts and such foreign resorts as Mentone, Madeira, Algiers, or Cairo is instituted the radical differences between the two classes of resort become apparent. Thus at the British resorts in general the invalid must expect that during winter rain will fall on at least half the total number of days, and that on a very large proportion of these days out-door exercise will be hazardous or impossible; whereas in the Riviera the rainy days average only about five or six per month in winter, while in Egypt the rainfall is only nominal and many parts are absolutely rainless. Equally striking is the contrast if we take the average number of days of cloudless sunshine—so important to many invalids—at the different resorts. Without pretending to precision regarding a question in which precision is not attainable, we may safely say that for every day of cloudless sunshine available for the invalid during winter in the British islands there are five or six days at some of the most favoured Mediterranean resorts, and nine or ten in Egypt. Again, as regards the average relative humidity of the atmosphere, there is a great contrast between the 85 to 90 per cent. of British resorts and the 70 to 73 per cent. of Mentone, or the 58 per cent. of Cairo. Without going into further details we may say that, while the resorts upon the southern and south-western shores of England and Ireland possess great advantages, which should never be forgotten, they fall far below the favourite foreign resorts in such points as amount of sunshine, proportion of fine days, and facilities for out-door exercise.

Among foreign resorts there is a wide choice. The Western Riviera, including such resorts as Hyères, Cannes, Nice, Mentone, Monaco, Bordighera and San Remo, has a dry, bright and stimulating climate, with a very high proportion of sunshine and fine days, a remarkable configuration of coast, affording much protection from the north, charming scenery and ample accommodation. Its chief drawback is its windiness, the mistral or north-west wind being especially troublesome. The differences between sun and shade temperatures are considerable, sudden changes are common, and inflammatory affections of the lungs and pleura are somewhat frequent. At the same time, this region has undoubtedly one of the most enjoyable climates in Europe. It is a region in which the prudent patient, who observes times and precautions and medical regulations, will reap the maximum of advantage, and in which carelessness, ignorance and folly are most sure of speedy punishment. The Eastern Riviera, including such resorts as Nervi, Rapallo and Spezia, has a moister and more sedative climate than the Western Riviera, its northern screen of mountains is less perfect, and it possesses fewer attractions, natural and artificial. But it suits some patients for whom Cannes, Nice and San Remo are too stimulating.

Pau, Arcachon and Biarritz form a triad of adjacent resorts which may be considered together. Compared with the

Riviera, they possess a somewhat mild and moist climate, with a fair average of warmth and of sunshiny days, and are well adapted to cases where a moderately sedative influence is desired. Biarritz, by virtue of its position and exposure to winds from the Atlantic, is the least sedative of the three. These resorts are much inferior to those of the Riviera as regards the protection afforded by mountains in their vicinity.

Malaga possesses one of the best climates in Europe. The rainy days are said to number only 40 in the year, compared with 60 at Nice, 80 at Mentone, 88 at Madeira, 119 at Pau and 155 at Torquay. While the climatic advantages of Malaga are great, we may well pause before sending patients, especially pulmonary cases, to a large, busy and not too clean Spanish city. Malaga has the further drawback that it possesses very few natural attractions. Nevertheless, its remarkably fine climate must not be forgotten in any survey of European sanatoria.

Morocco and Algeria afford several notable resorts, such as Mogador, Tangier and Algiers. They possess a much larger proportion of warm days and a greater immunity from cold winds than any of the resorts on the northern shore of the Mediterranean. Still, owing to the frequency of sea breezes and the vicinity of high mountains, their climates are moister than might have been anticipated. Thus the annual rainfall at Algiers is thirty-six inches, considerably more than the average of England, and of this four-fifths or five-sixths fall during the winter season. The interior of Algeria affords several resorts on the verge of the Great Desert—such as Biskra—where the climatic conditions rival the warmth and sunshine of Egypt.

The land of the Nile possesses one of the most wonderful climates in the world. Here alone are found associated perpetual sunshine and practical rainlessness with verdure and fertility. The rainfall of Egypt varies from eight inches annually at Alexandria and one inch and a quarter at Cairo to *nil* at Luxor, where it is facetiously said to rain once in every 4000 years. With such a rainfall the number of dull and cloudy days is necessarily very small—almost perpetual sunshine may be said to prevail and a high degree of atmospheric dryness is attained. The drawbacks to such a climate as that of Egypt are the great contrast between the day and the night temperatures, owing to the intense energy of radiation, the glare of the sunlight and the plague of dust. The Egyptian climate is enjoyed to the fullest advantage during a well-planned voyage by dahabiyah up the Nile.

The high Alpine sanatoria—such as Davos, Wiesen, St. Moritz, Arosa and Maloja—present a winter climate sharply contrasting with those previously enumerated. In these latter the prevailing conditions are almost uninterrupted frost, a high average of sunshine and fine days, a high degree of the rarefaction of the air, great dryness of the atmosphere (the relative humidity being sometimes as low as 40 at Davos), a great contrast between sun, heat and shade temperature (a maximum in the sun of 150° or upwards being often associated with a temperature far below freezing point in the shade) and (at Davos) a remarkable freedom from winds and consequent stillness of the atmosphere. These meteorological conditions constitute a highly tonic and stimulating climate.

Madaira is the type of the warm, moist, equable and hence sedative climate. The latitude ensures a high degree

of winter warmth; the constant prevalence of moisture-laden sea breezes causes much atmospheric humidity. The rainfall is moderate and the average of fine days high, and there is practical immunity from fog and dust. The most notable feature of the Madeira climate is the remarkable equability of temperature, both as regards diurnal changes and seasonal range. Extremes of heat and cold are alike unknown, and the difference between in-door and out-door temperature and between that of day and night is only slightly appreciable.

We might easily extend our survey to more distant winter quarters. The South African highlands possess a dry, stimulating climate of great value in many cases, but the country is comparatively undeveloped and the comforts of life few. Australia and New Zealand present a great variety of climates, many of them possessing a high degree of salubrity. The climate of the former is in the main hot, dry and stimulating, but great differences necessarily exist. The most favoured parts for the purposes of the invalid are perhaps the highlands of New South Wales and Queensland. The climate of New Zealand is moister and cooler than that of Australia, and approximates in character to that of the more favoured parts of the British islands.

America presents many excellent winter sanatoria, such as Colorado, California and Florida. The first of these belongs to the class of dry inland climates of considerable elevation, the second to the class of dry marine climates, and the third to the class of moist marine climates.

We need hardly remind our readers that a climate is tonic and stimulating largely in proportion to its dryness, whether associated with heat or cold, and that the sedative character of a climate depends upon warmth, moisture and equability. Places possessing cold, moist climates present no advantages to the invalid, and hence are practically excluded from the list of useful sanatoria.

"No quid nimis."

### COUNTY COUNCILS AND THE REPORTS OF THEIR MEDICAL OFFICERS.

It was expected that the appointments of health officers to county councils would have some good effect on local boards, who had been somewhat negligent in sanitary matters. As yet not much has been done, the medical officers simply making a report on their analyses of the reports of the medical officers of health within their county, and also making recommendations as to the means which ought to be taken to prevent the pollution of rivers. Public bodies move slowly, so that we may yet hope that county councils will exercise a wise and wholesome influence over rural districts and their district councils (local boards) in the future. Recently the Ince Local Board have been exercised concerning a report of the medical officer to the County Council of Lancashire, which tells of their insanitary state and shortcomings. The clerk was instructed to frame a reply. Why not the medical officer of health? The chairman of the board, who is also a county alderman, is reported to have "interviewed" Mr. Sergeant before attending the board meeting. He said: "He thought it his duty before coming to that meeting to go to Preston to see the medical officer of health. He went prepared to champion the board; but how did the medical

officer reply? By producing the reports from their own medical officer that made statements bearing out his own report. He gave all credit to their medical officer for expressing himself on the importance of the matter for the first time. In one of his own reports the backyard premises in the district were described as in a filthy condition, and the letter drafted by the clerk proposed to put the matter right by denying it." Now if the county medical officer is to be taken to task for pointing out the insanitary spots in his area, what about the medical officer of health for the district; is he to be muzzled? In this very district, and read at the same meeting of the board, was the medical officer's report for the month, showing that there had been 39 cases of infectious disease—viz., scarlet fever, 13; typhoid fever, 11; diphtheria, 5; membranous croup, 2; erysipelas, 5; continued fever, 1; and puerperal fever, 2. Surely it was the intention of the Legislature, when the Local Government Act was passed which enabled county councils to appoint health officers, to aid the local medical officers of health to abolish these plague spots. \_\_\_\_\_

### THE PERILS OF ELECTRIC LIGHTING.

THE introduction of electric lighting is, thanks to the solicitude of the Legislature and the skill enlisted in the service of the Board of Trade, an industry which, its magnitude considered, has been attended hitherto with singularly little loss of life and personal injury. The inquest held on Monday last by Mr. Drew upon the body of a workman employed by the House-to-House Electric Lighting Company, who had met his death by incautiously "short-circuiting" a lighting current, disclosed no new and unsuspected danger and gave no occasion for regret except for the human frailty which led a young man to in ur needless risk by neglecting the most elementary precautions in the conduct of his work. It would seem that in this case the paradox is true that if the electric lighting current were less dangerous than it is people would handle it with greater circumspection than they do. A Ruhmkorff coil deals a smart blow if inconsiderately touched, and nobody does touch it inconsiderately, although it always, when in action, presents numerous surfaces which are highly charged with electricity. But a lighting main is apt to kill, and is therefore insulated with the greatest and most effective care. Hence accidents are rare, so rare that they cease to make an impression, and a heedless workman manipulates the mains with bare hands as if they were harmless as kittens. A pair of india-rubber gloves would make him quite safe, as he perfectly well knows, but he prefers to take the small and inconspicuous risk, and to have his hands unshackled for his work. It is matter for rejoicing that his confidence is not often misplaced, but when it is the consequences are lamentable, for a 2000-volt current is a foe that strikes in silence but seldom strikes in vain. \_\_\_\_\_

### OFFENCES AGAINST THE APOTHECARIES ACT.

THE judgment recently delivered, after deliberation by the Court of Queen's Bench, in the action of "The Society of Apothecaries v. Jones," has resulted in a definition of the nature of an offence under that Act which is not very easily derived from the words of the statute itself. It is there provided that if any person shall *act or practise* as an apothecary without due registration he shall "*for every such offence*" incur the prescribed penalty. The judges have held that the offence here spoken of is not the individual act, but a continuous course of conduct, so that although, as in the present case, three several acts may be proved against the offender, these are held to constitute only one offence. This decision supported a judgment to the same effect by the county court judge before whom the action was originally tried, and we observe that counsel for the Society

applied for leave—which, however, was refused—to carry the appeal farther. That the Society should be dissatisfied with an adverse ruling upon such a very difficult point of construction is natural enough, and if the question were entirely now we should think them very well advised in prosecuting the appeal with a view to obtaining the most authoritative decision which can be had. But, in truth, the question is not so new as it appears to have been thought to be both by the parties to the cause and the judges who decided it. The self-same question arose in the year 1824—that is to say, within ten years of the passing of the Act, when the Apothecaries' Society proceeded against a defendant named Bentley (or Warburton; there is some confusion in the report as to the defendant's name) to recover several penalties under this same section in respect of several acts alleged as so many separate offences. It was then held, as in the present case, that only one penalty had been incurred, and this must therefore be taken to have been the judicially settled construction of the section for a period of nearly seventy years. This case appears, as we have said, to have escaped the notice of all parties concerned in the more recent decision, and it is therefore the more noteworthy that the court should have, unwittingly as it were, followed and confirmed at the present date its earlier decision. The coincidence affords strong presumption that the decision is sound in law, and in any case we do not doubt that when once attention has been drawn to this old and seemingly forgotten judgment the Society of Apothecaries will be well content to acquiesce in an exposition of the law which has for so long a period enjoyed unchallenged currency.

#### THE REMOVAL OF HUMAN REMAINS FROM THE VAULTS OF A CITY CHURCH.
